## DEDICATÓRIA

À minha mãe, Flavia, e aos meus avós Arno e Aneide que foram fundamentais para eu trilhar meu caminho até o dia de hoje e muitas vezes tiraram de si para que eu pudesse realizar meus sonhos. Vocês sempre foram minha força e o maior exemplo para me tornar alguém melhor. Nada disso seria possível sem vocês.

Ao meu noivo, Fernando, que me conheceu no início do doutorado e acompanhou minha caminhada até esse momento. Você me inspira a ser alguém forte e confiante. Obrigada por ser meu porto seguro e acreditar em mim mais do que eu mesma.

## DEDICATÓRIA

À minha orientadora, profa. Dra Sandra Farsky, que sempre quis a melhor formação para seus alunos e faz de tudo ao seu alcance para isso. Que me acolheu em momentos difíceis e me mostrou que sempre somos capazes de superar nossos limites. Obrigada por acreditar em mim e me ajudar alcançar meus sonhos!

## AGRADECIMENTOS

À Fundação de Amparo a Pesquisa do Estado de São Paulo - FAPESP pela concessão do apoio financeiro durante o doutorado (Projeto nº 2018/26383-7), pela bolsa BEPE (Projeto nº 2022/05777-2) que me possibilitou alcançar a oportunidade de expandir meus conhecimentos na pesquisa.

À Faculdade de Ciências Farmacêuticas (FCF-USP) por proporcionar a oportunidade de fazer parte desse programa que me acolheu como aluna, pela infraestrutura e professores necessários para a minha formação.

À CAPES, pelo apoio ao desenvolvimento e consolidação do Programa de Pós-Graduação em Farmácia.

À meu querido orientador de iniciação científica e mestrado José Roberto Santin que me inspirou a ser uma cientista, que sempre acreditou em mim e me ajudou a trilhar o caminho do conhecimento desde a graduação.

À meus colegas e amigos de bloco 13B: Pablo, Silvana, Pamela, Luana, Vítor e André. E aos que já saíram de lá: Gustavo e Marina. Cada dia vivido no laboratório foi melhor por que vocês estavam lá para compartilhar as felicidades, angústias, almoços e cafés comigo.

À meu amigo Matheus Leão, que me ajudou a entender o mundo das nanocápsulas e transferiu todo seu conhecimento para mim, no início uma estranha, da melhor forma possível.

À meu amigo Pablo Scharf, que desde o primeiro dia que iniciei na USP foi um ombro amigo dentro e fora do laboratório. Que nunca mediu esforços para me ajudar e estar presente para me dar seus conselhos sinceros.

À minha amiga Silvana Sandri, uma pesquisadora com o conhecimento e o coração maiores do mundo. Seus ensinamentos foram são para a vida.

À minha amiga Pamela Pacassa, que me acolheu e fez do seu, o meu lar tem um momento que precisei de um ombro amigo. Que me ajudou a concluir diversos experimentos enquanto eu estava no BEPE.

À professora Soumita Das (Universidade Massachusetts Lowell) que abriu as portas de seu laboratório para me receber durante o BEPE.

À meu mentor do BEPE, Ibrahim M. Sayed (Universidade Massachusetts Lowell). Você mudou o destino do meu BEPE e me acolheu como uma de suas alunas. Obrigada por todo o conhecimento repassado e amizade.

À meus amigos Stefania Tocci e Noah Sout (Universidade Massachusetts Lowell) que dentro e fora do laboratório foram o motivo de eu aguentar os momentos difíceis e de solidão.

À meus colaboradores que foram essenciais para o desenvolvimento da minha tese e artigos publicados nesse período: Professora Márcia Fantini, Professor Marco Antonio Stephano, Dr Luís Cides e Dr. Pedro Oseliero, obrigada por me receberem em seus laboratórios e abraçarem esse projeto da SBA-15 junto conosco. Às professora Silva Guterres e Adriana Pohlmann que forneceram todo suporte científico para o desenvolvimento da MLNC. Ao Professor Lionel Gamarra e seu aluno Fernando que colaboraram para os experimentos de PET/SCAN e enriqueceram nosso trabalho.

## RESUMO

**BROERING, M. F. Novas formulações de Anexina A1 como estratégia terapêutica para a colite experimental. 2024. 316 f. Tese (Doutorado em Ciências) – Faculdade de Ciências Farmacêuticas, Universidade de São Paulo - SP, 2024.**

A Anexina A1 (AnxA1) é uma proteína de 37 kDa que controla o desenvolvimento da reação inflamatória inata, e favorece a eferocitose e o reparo tecidual. Em doenças inflamatórias intestinais (DIIs), tanto a AnxA1 endógena, como a sintética e o peptídeo sintético mimético ao N-terminal da proteína (Ac2-26) inibem o desenvolvimento de doença e induzem a cicatrização. O presente projeto teve o objetivo de obter novas formulações para carrear a AnxA1 recombinante (rAnxA1) ou o Ac2-26 e testar suas eficácias no modelo de colite experimental induzida pelo dextram sulfato de sódio (DSS, 0-6 dias) em camundongos C57Bl/6 machos. A rAnxA1 foi funcionalizada em nanocápsulas de núcleo lipídico de parede múltipla (MLNC) pela ligação  $Zn^{2+}$ , com alta eficiência de incorporação (92%) e administrada pelas vias oral, intravenosa ou intraperitoneal durante a fase latente da doença (6°-9° dia). Somente o tratamento intraperitoneal com MLNC-AnxA1 (12,5  $\mu\text{g/mL}$ ) reduziu significativamente os sinais clínicos da doença, restaurou a integridade da estrutura colônica e a proliferação celular, bem como aumentou expressão de junções celulares da barreira intestinal. Ainda, MLNC-AnxA1 induziu a polarização de macrófagos para o fenótipo M2 *in vivo* no tecido inflamado e *in vitro* após estímulo com lipopolissacarídeos (LPS) bacteriano. Na tentativa de obter uma formulação terapêutica com atividade por via oral, o peptídeo Ac2-26 foi incorporado em sílica mesoporosa ordenada SBA-15 e revestidos com Eudragit® L30-D55. A incorporação do peptídeo foi efetiva (88%) e a administração oral de Eudragit-SBA15-Ac2-26 (6°-9° dia; 200  $\mu\text{g/camundongo}$ ; 8 mg/kg) reduziu significativamente os sintomas clínicos e inflamação. De fato, ensaios de PET-SCAN mostraram que o SBA-15 permaneceu no intestino por até 16 horas após a administração e promoveu a liberação do peptídeo no intestino inflamado. Em cultura celular de epitélio (Caco-2), Eudragit-SBA15-Ac2-26 favoreceu a internalização de Ac2-26. Em conjunto, as duas estratégias experimentais de entrega do rAnxA1 ou Ac2-26 foram eficientes e os resultados obtidos sugerem que mais estudos devem ser realizados para a confirmação das estratégias de tratamento. Com o intuito de buscar ferramentas para ampliar estes estudos, durante estágio BEPE foram realizados estudos em cultura de células epiteliais baseado em células-tronco adultas diferenciadas *in vitro*. Os resultados mostraram que rAnxA1 ou Ac2-26 protegeram a integridade epitelial após desafio com LPS, pela regulação positiva da expressão das junções oclusivas e aderentes e redução da expressão de claudina-2, responsável pelo aumento da permeabilidade intercelular; pela modulação negativa de citocinas pró-inflamatórias CXCL-1 e MCP-1, e positiva de citocina anti-inflamatória IL-10. Desta forma, padronizamos um novo modelo de cultura celular ainda não testada para a AnxA1 ou Ac2-26, que poderá ser empregada para desvendar os mecanismos da MLNC-AnxA1 e do Eudragit-SBA15-Ac2-26.

## ABSTRACT

**BROERING, M. F. New formulations of Annexin A1 as a therapeutic strategy to experimental colitis.** 2024. 316 f. PhD thesis – School of Pharmaceutical Sciences, University of São Paulo- SP, 2024.

Annexin A1 (AnxA1) is a 37 kDa protein that controls the development of the innate inflammatory reaction, and favors efferocytosis and tissue repair. In inflammatory bowel diseases (IBDs), both endogenous and synthetic AnxA1 and the synthetic peptide mimetic to the N-terminal of the protein (Ac2-26) inhibit the development of disease and induce healing. The present project aimed to obtain new formulations to carry recombinant AnxA1 (rAnxA1) or Ac2-26 and test their efficacy in the experimental colitis model induced by dextran sodium sulfate (DSS, 0-6 days) in C57Bl/6 mice. rAnxA1 was functionalized into multiwall lipid core nanocapsules (MLNC) by Zn<sup>2+</sup> binding, with high incorporation efficiency (92%) and administered orally, intravenously or intraperitoneally during the latent phase of the disease (6<sup>o</sup>-9<sup>o</sup> day). Only intraperitoneal treatment with MLNC-AnxA1 (12.5 µg/mL) significantly reduced the clinical signs of the disease, restored the integrity of the colonic structure and cell proliferation, as well as increased the expression of intestinal barrier cell junctions. Furthermore, MLNC-AnxA1 induced macrophage polarization to the M2 phenotype *in vivo* in inflamed tissue and *in vitro* after stimulation with bacterial lipopolysaccharides (LPS). In an attempt to obtain a therapeutic formulation with oral activity, the Ac2-26 peptide was incorporated into ordered mesoporous silica SBA-15 and coated with Eudragit® L30-D55. Peptide incorporation was effective (88%) and oral administration of Eudragit-SBA15-Ac2-26 (6<sup>o</sup>-9<sup>o</sup> day; 200 µg/mice; 8 mg/kg) significantly reduced clinical symptoms and inflammation. PET-SCAN assays showed SBA-15 remained in the intestine for up to 16 hours after administration and promoted the release of the peptide in the inflamed intestine. In epithelial cell culture (Caco-2), SBA15-Ac2-26 favored the internalization of Ac2-26. Taken together, the two experimental delivery strategies for rAnxA1 or Ac2-26 were efficient and the results obtained suggest that more studies should be carried out to confirm the treatment strategies. In order to seek tools to expand these studies, during the BEPE internship, studies were carried out in epithelial cell cultures based on adult stem cells differentiated *in vitro*. The results showed rAnxA1 or Ac2-26 protected epithelial integrity after challenge with LPS, by upregulating the expression of tight and adherens junctions and reducing the expression of claudin-2, responsible for increasing intercellular permeability; by negative modulation of pro-inflammatory cytokines CXCL-1 and MCP-1, and positive modulation of anti-inflammatory cytokine IL-10. In this way, we standardized a new cell culture model that has not yet been tested for AnxA1 or Ac2-26, which could be used to unravel the mechanisms of MLNC-AnxA1 and Eudragit-SBA15-Ac2-26.

# *Introdução*

## Doenças inflamatórias intestinais

A inflamação é um complexo processo fisiopatológico desencadeado em resposta a agentes agressores ao organismo, sejam eles infecciosos ou não, que culmina na ativação de fatores plasmáticos e de células imunes e epiteliais, com a subsequente ativação de vias de sinalização inflamatória (MEDZHITOV, 2010). Dentre as diversas doenças de base inflamatória, encontram-se as doenças inflamatórias intestinais (DIIs), como a doença de Crohn (DC) e a retocolite ulcerativa (RCU), caracterizadas pela presença crônica e recorrente de inflamação no trato gastrointestinal, com ênfase no intestino grosso. Esses distúrbios, considerados idiopáticos, podem ter sua origem associada a fatores como alterações na microbiota intestinal, ambientais, autoimunidade e predisposição genética. Além disso, trata-se de condições incuráveis que alternam entre períodos de latência e remissão. Os principais sintomas dessas enfermidades incluem diarreia persistente, dores abdominais, presença de sangue nas fezes e fadiga. Ainda, cerca de 25% das pessoas acometidas podem apresentar alguma manifestação não intestinal, como lesões cutâneas, orais e oculares. Pacientes com DIIs têm risco significativo de desenvolvimento de câncer colorretal e as implicações sociais consideráveis decorrentes da situação debilitante enfrentada pelo doente (COLOMBEL; NARULA; PEYRIN-BIROULET, 2017; FEUERSTEIN et al., 2019; LEE; KWON; CHO, 2018; WILHELM; LOVE, 2017).

Entre 1990 a 2017 registrou-se um aumento considerável na incidência de DIIs em diferentes regiões do mundo. Um dos fatores associados a esse aumento inclui mudanças no estilo de vida e comportamento, exposição à poluição ambiental e alteração na dieta. Estes fatores estão associados às diferenças culturais, juntamente com a industrialização. Atualmente as maiores prevalências de DIIs encontram-se nos Estados Unidos, China e Europa Ocidental, com cerca de 150 casos para 100.000 habitantes. Houve aumento de aproximadamente 50% de prevalência e 68,75% de aumento da morbidade relacionada a DIIs quando comparados os períodos entre 1990 e 2019 (WANG et al., 2023). Contudo, no período entre 2016 e 2019, a morbidade das DIIs alcançou estabilidade em países ocidentais. Essa estabilização foi principalmente atribuída aos avanços nas terapias específicas desenvolvidas para o tratamento dessas condições (KAPLAN; NG, 2017; PARK et al., 2020; WANG et al., 2023).

O diagnóstico de DIIs ocorre comumente em pessoas com idade entre 15 e 35 anos e é baseado em uma combinação de sintomas, análises colonoscópicas e histológicas, além cultivo de fezes para descartar a possibilidade de outras infecções (MAGRO et al., 2017; SHIVASHANKAR et al., 2017). O diagnóstico diferencial de RCU e DC ocorre, principalmente, pela colonoscopia que avalia a aparência intestinal e coleta de tecido para biópsias seriadas de cada segmento intestinal. Na RCU, os pacientes apresentam lesões contínuas, marcadas por ulcerações, que se limitam ao cólon e se iniciam no reto e atingem até a região proximal, podendo atingir todo o cólon de forma ascendente (NIKOLAUS; SCHREIBER, 2007). A biópsia apresenta infiltrado celular majoritariamente de neutrófilos e se caracteriza por inflamação na região mucosa, podendo apresentar edema de cripta e alteração da histoarquitetura. Pacientes portadores de DC apresentam envolvimento em todo o trato gastrointestinal, com lesões em regiões alternadas, mas que acometem principalmente a região ileal na maioria dos casos. A biópsia pode apresentar características similares a RCU; no entanto, a inflamação ocorre de forma transmural e grande parte dos casos apresenta granulomas e o infiltrado celular é majoritariamente de células mononucleares (GEBUES et al., 2000; SILVERBERG FRCPC et al., 2005; WOLFSON et al., 1982).

Diferentes mecanismos podem estar associados a etiologia de DIIs, por se tratarem de doenças crônicas, remitentes-recorrentes e imuno mediadas, o que também acarreta complexidade da gênese dessas doenças (LINDEN et al., 2008) (Figura 1). A heterogeneidade no padrão de distribuição das DIIs ao redor do mundo indica a importância crucial dos fatores ambientais em seu desenvolvimento. Entretanto, é relevante observar que variações genéticas desempenham um papel significativo, influenciando as modificações principalmente no sistema imunológico (GRAHAM; XAVIER, 2020; SHI et al., 2019). Uma característica de pacientes com RCU é a redução da camada de mucina, a qual é responsável por manter as bactérias afastadas da barreira intestinal (JOHANSSON et al., 2014). Além disso, a redução do gene fucosiltransferase 2 (*FUT2*), que está associado a função da barreira mucosa, é relacionado ao aumento da suscetibilidade para o desenvolvimento de DC (MCGOVERN et al., 2010). A camada de mucina secretada sobre o epitélio intestinal é considerada uma barreira física e a primeira linha de defesa para impedir a invasão das bactérias luminiais (LINDEN et al., 2008).

**Figura 1.** Representação gráfica dos fatores envolvidos no desenvolvimento das DIIs

As DIIs são doenças multifatoriais e podem ter sua patogênese associada a uma ou mais condições simultaneamente. Fonte: o autor

Na RCU, o aumento da permeabilidade da barreira epitelial está associado a redução da síntese e secreção de mucina 2 (MUC2). Diferentes fatores podem estar relacionados a diminuição da espessura e composição do muco intestinal, como a presença de células calciformes (*goblet cells*) imaturas e a redução do número dessas células, responsáveis pela produção e manutenção do muco intestinal (GROOTJANS et al., 2013; SHAOUL et al., 2004). Pacientes com DC ou RCU também podem apresentar aumento de muco intestinal, no entanto tal característica não impede a permeação de bactérias pela barreira epitelial. Nesses casos é observado alterações estruturais secundárias no muco, como perda da função viscoelástica. A qualidade do muco intestinal está intimamente relacionada à composição da microbiota intestinal e a produção de seus metabólitos, uma vez que pacientes com DIIs apresentam comumente defeitos em glicosilação e sulfatação na estrutura do muco, tornando-o ineficaz como barreira (GROOTJANS et al., 2013; PARIKH et al., 2019).

Além disso, muitas alterações genéticas associadas ao desenvolvimento de DIIs ocorrem especificamente entre a interação do sistema imune e a microbiota. Uma das modificações genéticas mais notáveis e correlacionadas às DIIs refere-se a alterações no gene responsável pela codificação do receptor intracelular de domínio

de oligomerização de ligação a nucleotídeos 2 (NOD2), cuja função é o reconhecimento de componentes da parede bacteriana e a promoção da função antimicrobiana celular por meio da ativação de vias pró-inflamatórias. A alteração no gene NOD2 está associada à modificação do microbioma e aumenta a suscetibilidade e recorrência à DC (KOBAYASHI et al., 2005; MUKHERJEE et al., 2019; SHARMA et al., 2023).

A disbiose, reconhecida como um fator significativo para a manifestação e evolução das DIIs, destaca-se pela influência crucial da composição da microbiota intestinal no desenvolvimento dessas condições. Bactérias simbióticas presentes no intestino reforçam a barreira anti-inflamatória e a regulação das células imunes intestinais (PICKARD et al., 2017). A ruptura desse equilíbrio mutualístico que existe no microambiente intestinal leva a redução de metabolitos anti-inflamatórios produzidos por essas bactérias, como ácidos graxos de cadeia curta (*short-chain fatty acids* – SCFA), butirato e ácido indoleacrílico (FRANK et al., 2007; GAUDIER et al., 2004; WLODARSKA et al., 2017). Adicionalmente, a exposição a poluentes ambientais, como elevados níveis de dióxido de enxofre (SO<sub>2</sub>) e dióxido de nitrogênio (NO<sub>2</sub>), está correlacionada à maior propensão ao desenvolvimento das DIIs (MOLODECKY; KAPLAN, 2010).

Os intestinos desempenham papel vital no funcionamento do corpo humano, destacando-se pelo tecido epitelial que se auto-renova de forma rápida, superando outros mamíferos. As vilosidades e microvilosidades das criptas intestinais, presentes em ambos os intestinos delgado e grosso, são essenciais para a absorção de nutrientes e na preservação da homeostase, oferecendo respostas imunes contra bactérias do microbioma e patógenos (BARKER, 2014; BARKER et al., 2007; DE SOUSA E MELO; DE SAUVAGE, 2019). A estrutura e integridade das criptas são mantidas pela renovação eficiente do epitélio intestinal, que se completa a cada 7 dias. Nas DIIs ocorre a perda da integridade de junções celulares que compõem o epitélio intestinal. Estas junções, compostas por proteínas transmembranares e citosólicas, se subdividem em *tight-junctions*, *adhesion-junctions* e desmossomos, desempenhando um papel crucial na coesão entre as células intestinais. Essa coesão forma a barreira intestinal, essencial para a homeostase do trato gastrointestinal. (AHMAD et al., 2014; GÜNZEL; YU, 2013; RESCIGNO, 2011; ZEISSIG et al., 2007).

A principal função das junções é atuar como um “portão” que sela o espaço paracelular, regulando a entrada de moléculas por esse espaço e formando canais que possibilitam a entrada de nutrientes (CHELAKKOT; GHIM; RYU, 2018; DIAMOND, 1978). As *tight junctions* estão localizadas na região apical das células e são compostas por diferentes proteínas transmembranas e citosólicas, dentre elas estão as zonulas de oclusão (ZOs), claudinas e ocludinas. Enquanto as junções de adesão estão localizadas em uma região subapical e são compostas por filamentos de actina e citoqueratina. Abaixo das junções de adesão estão localizados os desmossomos que interagem com as proteínas de junção de adesão e juntas fazem a forte adesão celular (FARQUHAR; PALADE, 1963).

Alterações na expressão e funcionamento das proteínas presentes nas junções epiteliais estão associados ao desenvolvimento de doenças, uma vez que essas agem em conjunto e interagem entre si. A expressão de ocludina no tecido é igualmente correlacionada com a integridade da barreira, sendo a mais abundante junção expressa por essas células. As claudinas, em especial a claudina 2 é responsável pela formação dos canais de água na região paracelular e o aumento da expressão dessa proteína é associado a ampliação da permeabilidade de barreira nas DIIs (CHELAKKOT; GHIM; RYU, 2018; HARHAJ; ANTONETTI, 2004; ZEISSIG et al., 2007). Por outro lado, o aumento da expressão das claudinas 1, 5 e 8 é correlacionado ao aumento da integridade da barreira epitelial (GÜNZEL; YU, 2013). ZO-1 é responsável por interagir com ocludina, claudinas e junções de adesão formando ligações através da interação com proteínas do citoesqueleto celular F-actina e miosina (CUNNINGHAM; TURNER, 2012).

O controle da expressão das junções ocorre de maneira altamente regulada. Embora muitos dos mecanismos que envolvem a regulação dessas proteínas sejam ainda desconhecidos, sabe-se que a resposta imune exerce grande papel na sua regulação. Enquanto o fator de crescimento transformador  $\beta$  (TGF $\beta$ ) atua aumentando a integridade pela regulação positiva de claudina 1 (HOWE et al., 2005), o fator de necrose tumoral  $\alpha$  (*tumoral necrosis factor*  $\alpha$  – TNF $\alpha$ ) e o interferon  $\gamma$  (IFN $\gamma$ ) são capazes de atuar sobre a regulação negativa da integridade dessas junções. O TNF é capaz de alterar a expressão de ocludina, induzindo a internalização dessa proteína, enquanto o IFN $\gamma$  reduz a expressão de ZO-1 e ocludina (UTECH et al., 2005; WANG et al., 2005). Dado o fato de que DIIs são doenças imuno mediadas, o estudo das junções de adesão é crucial para a compreensão das DIIs (DIIs), sendo essencial

tanto para desvendar os mecanismos subjacentes à patogênese quanto para o desenvolvimento de abordagens terapêuticas eficazes.

### **O sistema imune na patogênese das DIIs**

O sistema imune que controla a homeostase intestinal é composto de um equilíbrio complexo entre a imunidade funcional (inata e adaptativa) e anatômica (mucosa e sistêmica). As células imunes na mucosa intestinal podem ser encontradas em linfonodos secundários e são, majoritariamente, compostas de linfócitos, macrófagos e células dendríticas que promovem o controle imune frente a antígenos inócuos (MALOY; POWRIE, 2011).

As células dendríticas, componentes essenciais do sistema imunológico, mantêm um contato contínuo com antígenos luminiais através de seus dendritos que permeiam as células epiteliais. Esta função de "vigilância" desempenhada pelas células dendríticas é crucial para a detecção de organismos estranhos, que podem manifestar-se como PAMPs (Padrões Moleculares Associados a Patógenos) ou DAMPs (Padrões Moleculares Associados a Dano). Este processo de vigilância está intrinsecamente associado ao controle rigoroso entre o que é considerado "self" e "non-self" pelo sistema imunológico. ao manterem uma vigilância constante, desempenham um papel crucial na detecção e resposta a ameaças potenciais, contribuindo para a homeostase imunológica e a defesa eficaz do organismo contra patógenos e lesões (FARACHE et al., 2013; GROSS; SALAME; JUNG, 2015).

Linfócitos B agem promovendo o equilíbrio na resposta a antígenos via imunoglobulinas (Ig) e podem adquirir seu fenótipo de plasmócitos e secretar a imunoglobulina A (IgA), para neutralizar os patógenos e toxinas sem a ativação da cascata inflamatória. Além disso, alguns pacientes com DC e RCU apresentam um subtipo de IgG contra a microbiota comensal, associado ao aumento da resposta inflamatórias nesses pacientes (BOURGONJE et al., 2022). Adicionalmente, outro estudo demonstrou que pacientes com RCU produziram autoanticorpos contra a integrina  $\alpha\beta6$ , que mantém a barreira epitelial através da adesão celular (KUWADA et al., 2021).

Os linfócitos T que residem no intestino passam por um processo de maturação nos órgãos linfoides associados ao intestino, conhecidos como *Gut-Associated Lymphoid Tissues* (GALTs). Destacam-se entre essas regiões os linfonodos

mesentéricos e as placas de Peyer, fundamentais componentes do GALT. Nesses órgãos, os linfócitos T adquirem características específicas de linfócitos intestinais antes de migrarem para regiões designadas do intestino delgado ou grosso em resposta a estímulos específicos. Os linfócitos T que se encontram no tecido epitelial intestinal podem ser subdivididos em duas categorias principais: as células intraepiteliais (LIE) e os linfócitos T localizados na lâmina própria. As LIE desempenham um papel crucial na regulação da autoimunidade e na promoção da tolerância intestinal. Por outro lado, os linfócitos T presentes na lâmina própria estão diretamente envolvidos na resposta imunológica do intestino contra agentes infecciosos. As células não intraepiteliais (LIE) atuam na promoção da tolerância imunológica no intestino, desempenhando um papel fundamental na supressão de respostas autoimunes prejudiciais. Elas contribuem para a manutenção do equilíbrio entre a defesa imunológica e a prevenção de reações excessivas contra antígenos próprios do organismo. Por outro lado, os linfócitos T localizados na lâmina própria desempenham uma função predominante na defesa contra infecções no intestino. Estas células respondem a estímulos provenientes de patógenos, promovendo respostas imunes adaptativas eficazes para combater invasores microbianos e garantir a integridade do sistema gastrointestinal (AGACE, 2008; CAMPBELL; BUTCHER, 2002; MA; TAO; ZHU, 2019). Um breve resumo do microambiente intestinal em homeostase está ilustrado na Figura 2.

**Figura 2.** Tecido intestinal em homeostasia

Diferentes tipos celulares compõem a barreira epitelial e são fundamentais para manter a integridade do tecido. Na base da cripta intestinal se localizam as células que darão origem a todo o conjunto celular formador da barreira. Células tronco adultas e células de Paneth controlam a proliferação e formação da cripta. Células calciformes (*Goblet cells*), produzem o muco que reveste a barreira celular em contato com o lúmen intestinal com objetivo de reduzir o contato bacteriano e barreira. Essas células se alternam entre os enterócitos. Ainda, linfócitos intraepiteliais (LIE) localizados entre os enterócitos fazem o pepl de controle da autoimunidade frente a antígenos. Na região da lâmina própria o equilíbrio imune ocorre pela presença de células dendríticas, macrófagos residentes e linfócitos T e B. Células linfóides inatas (ILC) são encontradas no intestino e regulam tanto o sistema imunológico quanto a integridade da barreira epitelial pela produção controlada de citocinas, em especial as interleucinas (IL) 12, 18, 23 e 1 $\beta$ . Linfonodos mesentéricos e a placa de Peyer são tecido linfóides associados ao intestino ou *Gut-Associated Lymphoid Tissues* (GALT) e são responsáveis pela maturação de linfócitos T intestinais. Linfócitos B representam o sistema imune adaptativo liberando IgA (não ativa sistema complemento e cascata inflamatória). Fonte: o autor.

As células T desempenham papel crucial na patogênese das DIIs. Células T ativadas deslocam-se dos gânglios linfáticos mesentéricos para a corrente sanguínea, onde circulam de forma contínua e dirigem-se para a lâmina própria. Esse direcionamento ocorre por meio da interação entre a integrina  $\alpha 4\beta 7$  e a molécula-1 de adesão celular de endereçamento vascular (MAdCAM-1) (LAMB et al., 2018; MEENAN et al., 1997). Os linfócitos que migram para o compartimento epitelial exercem regulação positiva sobre a integrina  $\alpha E\beta 7$ , que interage com a E-caderina nas células epiteliais, promovendo a retenção dos linfócitos e amplificação da inflamação (CHANG; WHERRY; GOLDRATH, 2014; LAMB et al., 2016).

A resposta mediada por células T pode assumir diferentes fenótipos de acordo com o perfil de citocinas produzidas pelas células apresentadoras de antígenos. A resposta de células T efectoras CD4<sup>+</sup> do tipo T helper T<sub>H</sub>1 e T<sub>H</sub>17 estão associadas a ativação dos fatores de transcrição T-bet e ROR $\gamma$ t, respectivamente. A resposta do tipo T<sub>H</sub>1 promove o recrutamento de macrófagos, células *natural killer* e células T CD8<sup>+</sup> via produção de interferon- $\gamma$ , enquanto a resposta via T<sub>H</sub>17 promove o recrutamento de neutrófilos e produção de IL-17A, IL-17F e IL-22. Ambos perfis celulares podem ser observados em pacientes com DC e RCU, no entanto os níveis de IL-17 são consideravelmente mais altos em pacientes com DC (BRITTON et al., 2019; FUJINO, 2003). No quadro de RCU a resposta das células T ocorre por meio da ativação de células T<sub>H</sub>2 via fator de transcrição GATA-3 e tem como característica a produção das citocinas IL-5 e IL-13, associadas à ruptura das células epiteliais, além de IL-4, IL-6 e TNF $\alpha$  (FUSS et al., 2004) ; ou T<sub>H</sub>9 produzindo IL-9 (KURMAEVA et al., 2014).

Outro subtipo celular proveniente do progenitor linfóide que está presente na mucosa intestinal tanto em períodos de homeostase quanto de infecção são as células linfóides inatas (ILCs). Constituindo uma subcategoria especializada do sistema imunológico, as ILCs manifestam tanto similaridades fenotípicas quanto funcionais com linfócitos T, sendo estrategicamente localizada em locais caracterizados por uma exposição intensificada a influências externas, como a mucosa intestinal, onde as infecções iniciais são propensas a ocorrer. Diferentemente de outras células que respondem a estímulos diretos, as ILCs respondem primordialmente a sinalização por citocinas provenientes tanto de células imunes quanto epiteliais (BERNINK et al., 2013; SIMONI et al., 2017; YOO; OH, 2023; ZENG et al., 2019).

As ILCs desempenham um papel significativo na patogênese das DIIs. A interação sinérgica de diversas citocinas pode induzir alterações substanciais no microambiente. O ciclo de ativação e plasticidade entre ILC1 e ILC3 é modulado pela produção significativa de citocinas, incluindo IL-12, IL-18, IL-23 e IL-1 $\beta$  por macrófagos e células dendríticas. A ativação de ILC1 resulta na produção de TNF $\alpha$  e IFN $\gamma$ , causando danos diretos à barreira epitelial. Por outro lado, a ativação de ILC3 é desencadeada por estímulos de IL-1 $\beta$  e IL-23, culminando na liberação de IL-12, IL-22, IL-17 e GM-CSF. O GM-CSF, por sua vez, induz células dendríticas (DCs) e macrófagos a gerar ácido retinoico, o qual também ativa ILC1, amplificando o ciclo inflamatório associado a esse subtipo celular (BERNINK et al., 2013; SIMONI et al., 2017; YOO; OH, 2023; ZENG et al., 2019).

Após permear a barreira epitelial, as bactérias são reconhecidas por macrófagos e células dendríticas, por meio de receptores do tipo toll (*Toll-like receptor* - TLR), capazes de distinguir os antígenos bacterianos, como o LPS (HART et al., 2005). Desta forma, ocorre a ativação de vias inflamatórias e fatores de transcrição responsáveis pela propagação do sinal inflamatório e perpetuação da resposta. O fator nuclear *kappa* B (NF- $\kappa$ B) é um dos mais reconhecidos pelo seu papel inflamatório, resultando no aumento de citocinas, como o TNF- $\alpha$ , IL-1 $\beta$ , IL-6, IL-12 e IL-23, entre outras (A JERSMANN et al., 2001; KAPLAN; JESS, 2016; ZHANG et al., 1999). Citocinas e quimiocinas atuam na sinalização celular para promover a quimiotaxia de células imunes para o sítio inflamatório. Os neutrófilos migrados para esse tecido assumem um papel microbicida fundamental para conter a infecção desencadeada pela translocação bacteriana, operando por meio da liberação das armadilhas extracelulares de neutrófilos (*neutrophil extracellular traps* - NETs), compostas por cromatina e proteínas dos grânulos intracelulares (BRINKMANN, 2004); grânulos contendo mieloperoxidase e elastase, bem como a geração de espécies reativas de oxigênio (ROS) e de nitrogênio (RNS) exercem funções líticas sobre as bactérias (BJERG BENNIKE et al., 2015), além de secretarem inúmeras citocinas pró-inflamatórias que contribuem para a exacerbação do processo inflamatório (HELLER et al., 2008; STEEL et al., 2011).

Dentre os mediadores que exercem papel fundamental na patogênese das DIIs, vale ressaltar o TNF $\alpha$ . Esse mediador solúvel produzido por macrófagos, neutrófilos, linfócitos e células epiteliais promove aumento da expressão de moléculas de adesão

pelas células endoteliais, induzindo o aumento da migração de células imunes (SANDBORN; HANAUER, 1999). O remodelamento tecidual, via fibroblastos com aumento de metaloproteinases e síntese de colágeno, contribui para ulceração e degradação da mucosa, além de contribuir para o aumento da permeabilidade das células epiteliais intestinais, o que leva a prejuízos na função de barreira (PALLONE et al., 2003; LOUIS, 2001).

Macrófagos são células da resposta inflamatória inata, a partir do reconhecimento antigênico associado tanto PAMPs quanto DAMPs. No entanto, essas células também são as principais responsáveis pelo processo ativo de resolução do processo inflamatório. O processo inflamatório intestinal pode progredir de duas formas: (1) cronificação e (2) resolução (MANTOVANI; BONECCHI; LOCATI, 2006; SCHETT; NEURATH, 2018). As DIIs são doenças inflamatórias com um curso crônico associado também a perda de tolerância dos macrófagos intestinais frente aos antígenos. Durante o processo inflamatório intestinal, ocorre o acúmulo de macrófagos imaturos que contribuem para a ativação de células  $T_H1$  e  $T_H17$  via citocinas IL-12, IL-23 e IL-1 $\beta$  e cronificação da inflamação (BAIN et al., 2013, 2014). A perda da função tecidual consequente da resposta inflamatória crônica e exacerbada, bem como a resposta inflamatória inefetiva estão associadas a necessidade de cirurgia em casos de DIIs (HWANG; VARMA, 2008).

O curso natural de uma inflamação é a resolução do processo e diversos mediadores proteicos e lipídicos estão associados a esse evento celular. Os principais eventos celulares associados à resolução da inflamação são: (1) redução da quimiotaxia de neutrófilos; (2) apoptose dos neutrófilos presentes no tecido; (3) mudança fenotípica dos macrófagos; (4) remoção desses neutrófilos apoptóticos por meio da eferocitose realizada pelos macrófagos (SERHAN; SAVILL, 2005; SCHETT; NEURATH, 2018; SUGIMOTO et al., 2019). Dentre os mediadores lipídicos que contribuem para a resolução, destacam-se a lipoxina A4, resolvina D1, resolvida E1 e a maresina 1 (UDERHARDT et al., 2012). As principais citocinas associadas são a IL-10 e o TGF $\beta$ , responsáveis pela diferenciação de macrófagos inflamatórios M1 em macrófagos anti-inflamatórios M2, reparo tecidual e apoptose de neutrófilos (LOPES et al., 2016; POE et al., 2013; SCHETT; NEURATH, 2018). Além disso, outros mediadores contribuem para completar o ciclo de resolução como o ligante indutor de apoptose relacionado ao fator de necrose tumoral (TRAIL) produzido por linfócitos T (MCGRATH et al., 2011), o ligante de Fas (FASL) (BROWN; SAVILL, 1999) e a

proteína AnxA1, que está relacionada a todos os eventos que envolvem a resolução da inflamação (PERRETTI, 2012; PERRETTI; D'ACQUISTO, 2009a).

Alguns dos principais eventos que promovem a resposta inflamatória e a resolução do processo inflamatório nas DIIs bem como a sua complexidade celular e molecular estão exemplificados na Figura 3.

**Figura 3.** A resposta inflamatória e resolutive que ocorre nas DIIs.

A figura representa os diversos eventos celulares que promovem o estabelecimento da resposta inflamatória (esquerda) e a resolução do processo inflamatório relacionada principalmente ao papel dos macrófagos (direita). Fonte: o autor.

## Terapias atuais e suas limitações

O tratamento das DIIs é baseado em principalmente em terapias que tentam controlar o processo inflamatório. A determinação da classe medicamentosa a ser utilizada é individualmente avaliada entre cada paciente e escolhida com base nos sintomas clínicos e estadiamento do grau da doença. A utilização de apenas uma das opções encontradas atualmente não resolve de forma efetiva os danos durante a fase ativa da doença, e a intervenção terapêutica precoce pode alterar o curso natural da doença e prevenir complicações irreversíveis (IM et al., 2018). Inicialmente, em casos considerados leves a moderados, as estratégias terapêuticas utilizadas são aminosalicilatos, como o 5-ASA, e corticosteroides. Os aminosalicilatos são potentes na redução da inflamação e utilizados para manter a remissão da doença, sendo a sua utilização isolada muitas vezes ineficaz; ademais, estudos realizados na década de 90 já demonstravam seus efeitos adversos, como por exemplo, quadros de artrite, aplasia de medula, nefrotoxicidade, pancreatite e pericardite, os quais comprometem a utilização destes agentes para a terapêutica (LIN; HINE, 1994; WILLIAMS et al., 2011). (MAGRO et al., 2017).

Um estudo realizado por Miyoshi et al., (2018) avaliou pacientes em estado ativo da UC e pacientes em remissão, onde ambos os pacientes apresentaram agravamento dos sintomas da doença, principalmente de sangramento, fato esse observado na também na reexposição ao fármaco, sugerindo o aminosalicilato como agravador da doença. A associação de 5-ASA e corticoides com medicamentos da classe das tiopurinas, como a azatioprina, também é protocolo de tratamento. Tiopurinas atuam como “antimetabólitos”, incorporados aos ácidos nucleicos e inibem vários genes da inflamação intestinal e do tráfego de leucócitos para o intestino (MIELE et al., 2020; NEURATH, 2010). No entanto, o uso de tiopurinas apresenta diversos efeitos adversos, como intolerância gastrointestinal, mielossupressão, hepatite, pancreatite e síndrome semelhante à gripe (CHAPARRO et al., 2013; CUFFARI et al., 1996). Ainda, a utilização de corticoides, como a prednisolona, dexametasona e budesonida, para o uso crônico é limitada devido a imunossupressão global que ocorre em tratamentos de longo prazo e outros numerosos efeitos adversos sistêmicos, como osteoporose, catarata e síndrome de Cushing (BUCHMAN, 2001).

O desenvolvimento das terapias biológicas revolucionou o tratamento das DIIs. Como mencionado anteriormente, a presença de TNF $\alpha$  está intimamente ligada a progressão da UC. Desta forma, estratégias terapêuticas surgiram visando neutralizar tal citocina através dos medicamentos biológicos (RIZZO, 2014). Essa abordagem é inserida nos casos considerados graves, onde os principais tratamentos empregados na UC, são os agentes anti-TNF $\alpha$  (infiximabe, adalimumabe e certolizumabe) que, na maioria das vezes, reduzem a necessidade de cirurgia e hospitalização e melhoraram a qualidade de vida dos pacientes ao mudar o curso da doença. Os anti-TNF $\alpha$  impedem a interação da citocina a seus receptores específicos na membrana celular e a conseqüente redução na ativação de células imunes e epiteliais (GUO; LU; BAI, 2013; KOBAYASHI et al., 2020; SOKOL; SEKSIK; COSNES, 2014). No entanto, parte dos doentes não são responsivos às terapias biológicas (VINCENT et al., 2013). Embora ainda sejam a principal opção de tratamento disponível tanto para RCU quanto DC, os tratamentos biológicos estão associados a reações de infusão, imunossupressão, infecções oportunistas e redução de sua eficácia com conseqüente atenuação ou perda de eficácia ao longo do tempo, secundária à produção de autoanticorpos (CLARK et al., 2007; STRIK et al., 2016).

Como já salientado, linfócitos T possuem papel crucial na patogênese das DIIs e contribuem para a instalação do processo inflamatório intestinal. A migração dessas células é dependente da liberação de diversas citocinas, selectinas e moléculas de adesão. Atualmente uma série de anticorpos monoclonais que atuam sobre essas proteínas já são utilizados na prática clínica enquanto outros com grande potencial ainda são em fase clínica de testes (KOBAYASHI; HIBI, 2023). No que diz respeito aos utilizados clinicamente destaca-se o vedolizumabe (Entyvio; Takeda Pharmaceuticals) é um anticorpo monoclonal específico contra a integrina  $\alpha 4\beta 7$ , uma molécula de adesão que participa do processo de migração de linfócitos (WYANT; FEDYK; ABHYANKAR, 2016). Vedolizumabe é utilizado em casos moderados a graves e como segunda linha de tratamento para pacientes que não respondem a terapias anti-TNF $\alpha$ , ou como primeira linha de bilógicos para pacientes que possuem limitações ao uso de anti-TNF $\alpha$ . Ainda a sua combinação com essa classe de aniticorpos monoclonais anti-TNF como o adalimumabe demosntrou resultados superiores ao uso isolado de ambas as terapias (SANDS et al., 2019). Outros anticorpos monoclonais utilizados no tratamentos de DIIs são os direcionados as citocinas IL-12 e IL-23 e suas subunidades. Ustekinumabe, por exemplo, um anticorpo

monoclonal que atua inibindo a via de sinalização dessas citocinas, responsáveis por induzir a diferenciação de linfócitos T CD4+ em T<sub>H</sub>1 e T<sub>H</sub>17 (LUO et al., 2010; SANDS et al., 2022).

O eixo microbiota/sistema imune é considerado um fator chave na patogênese das DIIs e um importante alvo farmacológico. A modulação do microbioma intestinal tem ganhado destaque como método alternativo e adjunto às terapias existentes. Pacientes com DIIs apresentam microbiota menos diversificada e descontrole da produção de metabólitos fundamentais para a regulação do sistema imune. Novas terapias incluem probióticos, prebióticos, simbióticos e, até mesmo transplante de microbiota fecal (PARAMSOTHY et al., 2017; AKUTKO; STAWARSKI, 2021). Neste caso, são realizadas combinações sintéticas de bactérias específicas e terapias personalizadas baseadas em perfis de microbiomas individuais de cada paciente e regulação de ácidos biliares secundários (YANG et al., 2021; ZHOU et al., 2022).

Considerando que as DIIs são caracterizadas por uma natureza crônica e ausência de cura definitiva, os pacientes podem enfrentar abordagens terapêuticas contínuas ao longo de suas vidas. O principal objetivo desses tratamentos é estabilizar o curso da doença, reduzindo, assim, o risco a longo prazo de intervenções cirúrgicas e perda de funções intestinais. Embora os agentes biológicos tenham representado avanços significativos na gestão das DIIs, promovendo mudanças substanciais nas estratégias terapêuticas, é importante observar que uma parcela considerável de pacientes ainda enfrenta a necessidade de adotar terapias alternativas. Isso decorre tanto de falhas na resposta aos tratamentos existentes quanto da ocorrência de efeitos adversos, ressaltando a complexidade do manejo clínico dessas condições e a importância contínua da pesquisa para aprimorar opções terapêuticas mais eficazes e personalizadas (AL-HORANI; SPANUDAKIS; HAMAD, 2022; HIGASHIYAMA; HOKARI, 2023).

## Anexina A1 e Ac2-26

A AnxA1 é uma proteína de 37 kDa, pertencente a superfamília das anexinas que inclui 13 moléculas com estruturas similares e com diferentes funções biológicas (BLACKWELL et al., 1980; ROTHHUT et al., 1983). As anexinas são caracterizadas estruturalmente por dois domínios terminais, onde uma pequena região N-terminal difere entre as isoformas e é responsável pelas atividades biológicas pela ligação da proteína a seus receptores na presença de  $\text{Ca}^{2+}$  (CROMPTON; MOSS; CRUMPTON, 1988) (Figura 4). Em condições basais, a AnxA1 é expressa de forma mais expressiva no citoplasma de neutrófilos, monócitos, macrófagos, eosinófilos, mastócitos, em algumas células tumorais, epitélios e, de forma mínima, em células T (GAVINS; HICKEY, 2012; RESCHER; GERKE, 2004). A síntese de AnxA1 é induzida por mediadores endógenos, sendo regulada principalmente pela ação de glicocorticoides e citocinas (BLACKWELL et al., 1980; PERRETTI; D'ACQUISTO, 2009a; SOLITO et al., 2003).

**Figura 4.** Estrutura proteica da Anexina A1 e seu peptídeo mimético derivado da região N-terminal, o Ac2-26.

Fonte: o autor

Em condições de ativação celular, a AnxA1 é rapidamente mobilizada do citoplasma para o meio extracelular. Pelo menos três mecanismos de secreção são propostos, sendo variáveis de acordo com o tipo celular, a saber: pela ativação de transporte dependente de ATP (*ATP-binding cassette*); pela fosforilação de serina amino terminal e subsequente passagem por domínios lipídicos da membrana para porção extracelular (PERRETTI; D'ACQUISTO, 2009; VONG et al., 2012) e; pela fusão e eliminação de vesículas contendo AnxA1 diretamente pela membrana

plasmática (DALLI et al., 2008; LEONI et al., 2015a; NOVIZIO et al., 2020; PESSOLANO et al., 2019). Ao ser liberada no meio extracelular, a AnxA1 secretada no microambiente inflamado pode atuar de forma autócrina, parácrina e justácrina. A AnxA1 fosforilada se liga aos receptores de peptídeos formilados 1, 2 e 3 (FPR1, FPR2 e FPR3), ativando vias de sinalização intracelular dependentes de ERK1/2 e MAPK para atuar sobre as células (HAYHOE et al., 2006; MCARTHUR et al., 2020b; PERRETTI; D'ACQUISTO, 2009). Os FPRs são receptores acoplados a proteína G e são expressos em diversos tipos celulares; a ligação ao FPR1 e FPR2 são as mais descritas para a modulação anti-inflamatória da AnxA1. Ainda, os peptídeos miméticos derivados da região N-terminal da AnxA1, como o Ac2-26, composto de 24 aminoácidos; Ac2-12, composto de 10 aminoácidos; Ac2-50, composto de 46 aminoácidos; Ac9-12, composto de 3 aminoácidos, também são capazes de se ligar ao receptor FPR2 e promover resposta celular similar a AnxA1. O peptídeo mimético mais relatado pela literatura é o Ac2-26 capaz de induzir a ativação não somente de FPR2, mas também de FPR1 (HAYHOE et al., 2006; LEONI et al., 2013, 2015a; LICE et al., 2022; PERRETTI et al., 2001, 2017; SUGIMOTO et al., 2016).

No que diz respeito ao seu papel anti-inflamatório, a AnxA1 age como regulador negativo na imunidade inata, atuando na transmigração e ativação de neutrófilos, monócitos e macrófagos (CHATTERJEE et al., 2005; GETTING; FLOWER; PERRETTI, 1997). Em animais geneticamente deficientes de AnxA1 ou tratados com bloqueadores de FPR2, a resposta inflamatória inata é exacerbada (BABBIN et al., 2008; LOCATELLI et al., 2014; MCARTHUR et al., 2020a; PERRETTI; GAVINS, 2003) e o tratamento com AnxA1 recombinante ou com seus peptídeos miméticos reverte a exacerbção da inflamação em animais deficientes de AnxA1 (GIROL et al., 2013a; QIN et al., 2015; VITAL et al., 2016). Anexina A1 (AnxA1), é inibidor da fosfolipase A2 (PLA2) de membrana. Essa ação inibitória tem implicações significativas na cascata do ácido araquidônico, uma vez que a PLA2 está envolvida na liberação desse precursor crucial. O ácido araquidônico, por sua vez, desencadeia a produção de eicosanoides, como a prostaglandina e outros mediadores lipídicos da inflamação (FLOWER; ROTHWELL, 1994; LIM et al., 1998). Sabe-se que a proteína é capaz de reduzir a diapedese de neutrófilos por meio da redução da expressão de moléculas de adesão celular responsáveis pelo rolamento e firme adesão dos leucócitos à parede vascular, que prejudica a subsequente migração destes para o foco de lesão (GETTING;

FLOWER; PERRETTI, 1997); modular a síntese de citocinas inflamatórias e anti-inflamatórias (CHIANG; SERHAN, 2006), além de atuar como mediador da ação anti-inflamatória do sulfito de hidrogênio (BRANCALEONE et al., 2014) e reduz a promoção da inflamação pela proteína translocadora (TSPO) (PANTALEÃO et al., 2018).

Além de modular o influxo de leucócitos para o foco de inflamação, em especial de neutrófilos e monócitos, a AnxA1 modula positivamente os processos de resolução da inflamação e reparo tecidual (PERRETTI; D'ACQUISTO, 2009). Estudos *in vivo* e *in vitro* mostram que a AnxA1 induz a apoptose de neutrófilo no foco de lesão e a subsequente fagocitose dos mesmos pelos macrófagos residentes e pela polarização de macrófagos para o fenótipo M2 (MCARTHUR et al., 2020; SCANNELL et al., 2007; SOLITO et al., 2003). Este mecanismo, que, em conjunto, é chamado de eferocitose é fundamental para a resolução da inflamação e sua indução é alvo na pesquisa e desenvolvimento de anti-inflamatórios (AIKAWA et al., 2018). Ademais, a AnxA1 endógena e exógena modula a angiogênese, a proliferação de fibroblastos e a secreção de citocinas anti-inflamatórias no modelo de regeneração tecidual, confirmando sua ação efetiva nos mecanismos de reparo. De fato, a literatura mostra, em modelos experimentais, que a AnxA1 é uma ferramenta como potencial na implantação de transplantes (COORAY et al., 2013; LACERDA et al., 2018).

Pelos mecanismos anti-inflamatórios e de reparo tecidual da AnxA1 citados acima, seu efeito benéfico em doenças inflamatórias tem sido amplamente demonstrado em modelos experimentais (BROERING et al., 2022; HARIDAS et al., 2019; LI et al., 2019a; LICE et al., 2022; MCARTHUR et al., 2020b). A AnxA1 emerge como um mediador crucial em condições de inflamação, desempenhando um papel resolutivo na recuperação tecidual. A expressão local de AnxA1 é essencial para a restauração do tecido afetado (LEONI et al., 2013; VERGNOLLE; COMERA; BUENO, 1995), especialmente na DC (REISCHL et al., 2020; SENA et al., 2013). Estudos recentes sugerem que níveis reduzidos de AnxA1 na DC estão associados a inflamação descontrolada, perpetuando a doença, e que análises diferenciais de AnxA1 podem indicar padrões de gravidade da doença (DE PAULA-SILVA et al., 2016a; SENA et al., 2015a; VERGNOLLE et al., 2004). Além disso, foi observada a expressão marcada de AnxA1 no cólon de pacientes com DC e que alcançaram remissão após o uso de infliximabe. No entanto, a falta de AnxA1 endógeno demonstrou ser prejudicial na progressão da colite experimental, resultando em piores

desfechos clínicos e histológicos, e uma taxa de mortalidade mais elevada. Esses resultados também indicam que a falta de AnxA1 pode impactar negativamente o tratamento com infliximabe (DE PAULA-SILVA et al., 2021).

De modo geral, a literatura indica que a secreção de AnxA1 é desencadeada durante os períodos de atividade da DII. Deficiências nesse mecanismo exacerbam a gravidade e prolongam a duração da doença. Da mesma maneira, intervenções terapêuticas capazes de potencializar os níveis de AnxA1 demonstram resultados mais eficazes (LEONI; NUSRAT, 2016). O uso do tripeptídeo MC12, derivado da estrutura da AnxA1, como tratamento na colite experimental em modelo de dimetil sulfóxido (DSS) e ácido trinitrobenzeno sulfônico (TNBS), ambos modelos que mimetizam a colite que atinge a mucosa e a região trans mural, respectivamente. MC12 demonstrou eficácia em reduzir parâmetros clínicos e inibir a ativação do fator de transcrição NF- $\kappa$ B (OUYANG et al., 2012).

Apesar de diferentes tipos celulares secretarem AnxA1 no cólon inflamado, a descoberta das vesículas extracelulares contendo AnxA1 secretadas por neutrófilos e células epiteliais intestinais proporcionaram o aprimoramento de um novo mecanismo de aplicação para a AnxA1 no tratamento da colite. O desenvolvimento de tecnologias com grande potencial de entrega direcionada capazes de regular negativamente o processo inflamatório e melhorar a cicatrização tecidual pode ser observado pelos resultados encontrados por Leoni et al. (2015), que utilizou nanopartículas poliméricas revestidas com colágeno IV contendo o peptídeo mimético Ac2-26 (Ac2-26-Col-IV) e aplicadas diretamente na mucosa intestinal ou intraperitoneal para o tratamento na colite experimental. Ainda, avaliando o potencial da mesma nanopartícula sobre a colite, Reischl et al. (2021) administrou de forma intraperitoneal Ac2-26-Col-IV para terapia perioperatória, que consistiu de avaliar a regeneração tecidual após excisão de parte do intestino. O modelo foi baseado em casos de pacientes que necessitam de remoção de parte do intestino resultante da cronificação do processo inflamatório e consequente necrose tecidual.

Apesar de apresentarem resultados promissores, a utilização de uma via de administração não invasiva é considerada de suma importância para a aderência do tratamento pelo paciente. Baseado nessa premissa, Li et al. (2019), desenvolveram um sistema de entrega capaz de liberar o peptídeo Ac2-26 em resposta a altas concentrações de ROS, atingindo o cólon inflamado de maneira específica, visto que

altas concentrações de ROS são encontradas em sítios inflamatórios. O tratamento promoveu regeneração tecidual e redução da resposta inflamatória gerada na colite experimental. Baseado no exposto acima, é clara a participação da AnxA1 como mediador para as DILs, tanto na fase ativa da doença como potencial tratamento para essas enfermidades crônicas e sem tratamento efetivo.

## **Nanotecnologia**

A nanotecnologia, uma das áreas mais promissoras do século 21, combina o estudo da nanociência com avanços tecnológicos para a produção de materiais em nanoescala, ou seja, produtos cujas dimensões estão na ordem de mil milionésimos de um metro ( $10^{-9}$  m) (DEAN; MANSOORI; FAUZI SOELAIMAN, 2005; MALIK; MUHAMMAD; WAHEED, 2023). As nanopartículas (NPs) são estruturas unidimensionais em nanoescala, com tamanhos variando de 1 a 100 nm. É importante observar que nanopartículas com dimensões superiores podem receber denominações específicas, como nanocápsulas ou nanorods. Essas estruturas podem ser compostas por diversos materiais, como polímero-lipídeo, polímero-metal, grafeno-metal, sílica-metal, ou podem consistir em apenas um componente, como polímero, lipídeo, sílica, metal ou carbono. A variação na dispersão e interação de seus componentes resulta em diferentes arranjos e composições, destacando a versatilidade dessas nanopartículas na aplicação de diversas tecnologias e campos, desde a medicina até a eletrônica (VERT et al., 2012).

Essa diferença dimensional confere às nanopartículas propriedades únicas que as tornam especialmente relevantes em áreas como diagnósticos avançados e terapêutica direcionada. Além disso, é importante destacar que as nanopartículas apresentam uma grande área superficial, uma característica intrínseca decorrente de suas dimensões reduzidas. Essa grande área superficial contribui para a notável capacidade de interação com uma variedade de componentes biológicos, como proteínas intracelulares e de membrana, enzimas e barreiras biológicas (ERDOĞAR; AKKIN; BILENSOY, 2019; FARAJI; WIPF, 2009; ZOLNIK et al., 2010). Devido à sua meticulosa engenharia que otimiza características físicas, químicas e mecânicas, as NPs diferem significativamente de materiais maiores, resultando em uma gama de novas aplicações, especialmente no campo biomédico (DENG et al., 2016; ZHANG et al., 2008).

As pesquisas relacionadas a administração de NPs têm sido direcionadas à diminuição dos efeitos adversos de certos fármacos, à otimização de doses e, entrega direcionada de determinadas substâncias (BERNARDI et al., 2012; DIMER et al., 2013). Nesse sentido, nanocapsulas constituídas de polímeros biodegradáveis têm se mostrado mais promissoras, além de melhorar a aplicabilidade terapêutica e reduzir a toxicidade identificada em outros tipos de NPs (BEGINES et al., 2020; GIRON et al., 2019; POHLMANN et al., 2013), como por exemplo, a deposição de partículas metálicas em órgãos filtrantes, muitas vezes proveniente da interação das NPs com o sistema retículo endotelial (YAO et al., 2019). Em relação à administração oral, as nanocapsulas poliméricas podem ajudar a ultrapassar a barreira gastrointestinal para moléculas com limitações de absorção por via oral (FRIEDRICH et al., 2014; RODRIGUES et al., 2016).

No contexto das DIIs, NPs de diferentes composições têm sido aplicadas para otimizar o uso dos tratamentos usuais das DIIs, os quais muitas vezes promovem efeitos sistêmicos indesejados, além de degradação da maior parte do medicamento no TGI. Estudos demonstraram que a nanoencapsulação de NPs contendo 5-ASA reduziu a degradação do medicamento e seus efeitos sistêmicos relacionados ao uso da medicação, sendo até 80% absorvido no cólon (MLADENOVSKA et al., 2007; VARSHOSAZ; JAFFARIAN DEHKORDI; GOLAFSHAN, 2006). Efeitos semelhantes foram encontrados com a nanoencapsulação de budesonida ligada a NPs de PLGA/Eudragit®S100, capaz de liberar o corticoide no cólon em concentrações efetivas (ZHOU; QIAN, 2018).

Em relação aos tratamentos com biológicos, foi descrito recentemente pelo grupo de Kim et al. (2020) um lipossoma revestido com Eudragit®-S100 contendo infliximab. Os lipossomas são principalmente compostos de fosfolipídios, e a taxa de liberação depende do número de bicamadas fosfolipídicas, podendo interagir de forma eficiente com o tecido intestinal. O estudo demonstrou que a entrega do fármaco ocorreu de forma direcionada no cólon, promovendo redução da ação do TNF $\alpha$  de forma mais eficiente do que pelo tratamento com infliximab de forma clássica e, ainda, reduziu os efeitos adversos (KIM et al., 2020). Outros compostos não utilizados na prática clínica também demonstraram eficácia quando encapsulados. Neste sentido, o ácido glicirrízico foi encapsulado em nanocarreadores de PLGA- Eudragit®-S100,

responsivos ao pH, que promoveu entrega eficiente no cólon e cicatrização da mucosa em curto prazo (ZEESHAN et al., 2019).

As pesquisas com NCs de núcleo lipídico tiveram início em meados dos anos 2000, quando um híbrido de NCs biodegradável, foi desenvolvido pelo grupo das professoras Adriana Pohlmann e Silvia Guterres, da Universidade Federal do Rio Grande do Sul (UFRGS). Alterações supramoleculares das partículas foram realizadas, como a adição do lipídeo sólido, monoestearato de sorbitano disperso no núcleo lipídico líquido das NCs (GUTERRES; ALVES; POHLMANN, 2007; JÄGER et al., 2009; VENTURINI et al., 2011). A estrutura supramolecular proposta para as nanocapsulas de núcleo lipídico (LNCs) consiste de um núcleo com característica organogel, e uma parede polimérica situada na pseudointerface óleo-água (POLETO et al., 2012). Além disso, o desenvolvimento de uma estratégia de formação de camadas pela interação eletrostática das substâncias, permitiu a transformação da natureza aniônica para catiônica pela adição e revestimento com quitosana, formando a nanocápsula de núcleo lipídico multicamadas (*multiwall lipid nanocapsules* - MLNC). A formação da MLNC se baseia da interação eletrostática entre o grupo amônio da quitosana e grupos carregados negativamente na superfície da LNC (BENDER et al., 2012).

A partir da MLNC, Bender et al., (2014) desenvolveram uma estrutura composta pelo complexo ligante metal-quitosana-lectina, usando zinco ( $Zn^{2+}$ ) para funcionalizar a superfície das nanocápsulas biodegradáveis. Esse metal reage com grupamentos de histidina da proteína, permitindo a complexação a estrutura da nanocapsula. As substâncias ativas, de acordo com suas características físico-químicas, podem localizar-se na fase dispersante, adsorvida na parede polimérica, particionada entre a fase dispersante e o nanocarreador, ou ainda no interior lipofílico da partícula. Dessa forma, as LNCs apresentam capacidade de controlar a velocidade de liberação de uma substância encapsulada (JÄGER et al., 2009), a rigidez particular e a capacidade de penetração em tecido biológico (FIEL et al., 2011, 2013).

Diversos estudos têm evidenciado que as nanocápsulas são uma opção promissora para otimizar a terapêutica de doenças (FRANK et al., 2015; GIRON et al., 2019; SMITH et al., 2020). Em um trabalho utilizando LNC, contendo indometacina carregada no núcleo, utilizadas no tratamento de glioblastoma *in vivo* por via oral, foi observada a capacidade da LNC de atravessar a barreira gastrointestinal e hematoencefálica de forma passiva, demonstrando maior acúmulo e retenção desses

fármacos encapsulados no tecido cerebral. Além disso, foi observada que tanto a administração pela via oral, quanto intraperitoneal não apresentaram diferenças na concentração do fármaco do tecido cerebral, destacando que não há impedimento na eficácia dos tratamentos NPs quando administrados por diferentes vias (RODRIGUES et al., 2016). Ainda, trabalhos que avaliaram o potencial antiproliferativo de tratamentos associados a MLNC sobre células cancerosas observaram efeitos consideravelmente maiores sobre a redução da proliferação de células de cancer de mama *in vitro* para MLNC-bromelina, quando comparado a bromelina não conjugada (OLIVEIRA et al., 2017) e de células de melanoma *in vivo* e *in vitro* utilizando LNC contendo acetileugenol no núcleo (DREWES et al., 2017). Além disso, a administração via oral e intraperitoneal de LNC contendo tracrolimos, um medicamento utilizado como profilaxia para transplante de órgãos sólidos, demonstrou redução significativa no número de leucócitos migrados, sendo sua efetividade equivalente em ambas as vias utilizadas e capaz de atravessar o trato gastrointestinal (TGI) sem ser degradado (FRIEDRICH et al., 2014).

Embora as LNCs permitam o carreamento de compostos ativos no seu núcleo lipídico, a plataforma desenvolvida permite a funcionalização e o carreamento de substâncias também ligadas a parede polimérica da nanocápsula, como por exemplo, os anticorpos direcionados a fração eletronegativa de lipoproteína de baixa densidade (LDL), utilizado por Cavalcante et al. (2021) e anticorpo específico para molécula de adesão celular endotelial plaquetária (anti-Pecam-1), utilizado por De Castro Leão et al. (2021), ambas MLNCs direcionadas para tratamento intravenoso da aterosclerose. Com base na formulação da MLNC, que possibilita a funcionalização da estrutura com proteínas biologicamente ativas, e visando o potencial terapêutico associado à AnxA1 para controlar o processo inflamatório, surgiu a perspectiva promissora de combinar a plataforma MLNC conjugando-a à AnxA1 como um potencial tratamento para as DIIs.

### **Micropartícula mesoporosa ordenada**

O avanço na combinação de diferentes materiais com potencial terapêutico tem viabilizado a criação de novas abordagens terapêuticas (ANSELMO; MITRAGOTRI, 2016; LIN; HURLEY; HAYNES, 2012). Nos últimos 10 a 15 anos, progressos

significativos foram alcançados na adaptação de estruturas em mesoescala. Dentre esses avanços, a organização de materiais mesoporosos se destaca como um exemplo representativo. Até os anos 1980, os materiais em mesoescala apresentavam poros que limitavam-se a 1,2 nm. A motivação para a pesquisa desses elementos surgiu da necessidade de desenvolver materiais com mesoporos de maior dimensão, capazes de atender às demandas práticas. A partir da descoberta da modelagem desses componentes surgiram as micropartículas mesoporosas. Esse material apresenta uma extensa área superficial composta por nanoporos de tamanhos ajustáveis que possibilitam a adsorção eficiente, carregamento de moléculas e íons-alvo, proporcionando acesso e difusão eficientes à superfície (DAVIS, 2002; KRESGE et al., 1992; YANAGISAWA et al., 1990; ZHAO et al., 1998a). O primeiro material da classe das sílicas mesoporosas a ser obtido com sucesso foi MCM-41 (*Mobil Composition of Matter*) e sua aplicação era primordialmente para catalise de reações. Desde então, nas últimas duas décadas, houve a incorporação de materiais de sílica mesoporosa para o desenvolvimento dessas estruturas em novos formatos, e ajuste do tamanho dos poros apenas controlando a estrutura e o tamanho das moléculas de surfactante na reação (BECK et al., 1992; KRESGE et al., 1992).

A sílica mesoporosa do tipo SBA-15 (*Santa Barbara Amorphous No. 15*) foi proposta inicialmente em 1998, apresentando características melhores do que a MCM-41. Com o objetivo de fornecer alta resistência térmica, hidrotermal e mecânica, a síntese desses materiais mesoporosos acontece por um processo denominado modelagem por cristal líquido, a qual utiliza como base o treta-etil ortosilicato (TEOS). Considerada um marco na síntese das micropartículas mesoporosa, a SBA-15 adquire um alto grau de ordenação resultante da utilização de um molde polimérico, que em meio ácido, aliado à hidrólise de TEOS, resulta na condensação dos complexos  $\text{SiO}_2$  para formar redes tridimensionais de  $\text{SiO}_2$  sobre a estrutura de micelas formadas pelo molde polimérico (LAN; ZHAO, 2022; ZHAO et al., 1998a, 1998b). A estrutura da SBA-15 apresenta um grande número de grupos silanol (Si-OH) que são importantes para a ligação de proteínas na superfície da sílica, além de excelentes propriedades, como estrutura hexagonal altamente ordenada, mesoporos grandes e ajustáveis (8–50 nm) e alta estabilidade térmica e mecânica como resultado da grande espessura da parede de sílica (YIU; WRIGHT; BOTTING, 2001; ZHAO et al., 1998a, 1998b).

A utilização biológica da sílica mesoporosa demanda características específicas, como um tamanho de poro moderado (inferior a 200 nm) e uma ampla

área superficial, favorecendo o contato eficaz com tecidos biológicos. Essas características fornecem a SBA-15 grande potencial para aplicação em entrega de substâncias. Ainda, a funcionalização de SBA-15 com grupos como amina, tiol, nitrila, fenila e cloro para a imobilização de proteínas na sílica mesoporosa (YIU; WRIGHT; BOTTING, 2001). Observando as características como tamanho, formato, superfície e presença de surfactantes, além de outros fatores como dose e via de administração, que são cruciais para se obter um perfil seguro de uso, tomam a SBA-15 um material com grande capacidade de biocompatibilidade e baixa toxicidade *in vivo* (HUDSON et al., 2008; SOUID et al., 2012).

A utilização de SBA-15 como um sistema de entrega controlada de substâncias de diferentes propriedades químicas é extensivamente estudada (GKILIOPOULOS et al., 2022; PROKOPOWICZ et al., 2019; XU; RIIKONEN; LEHTO, 2013). A estrutura de sílica mesoporosa pode contribuir para o carregamento seguro de estruturas proteicas, sendo capaz de proteger essas substâncias contra a degradação pelo pH e ações enzimáticas (PERDEW; BURKE; ERNZERHOF, 1996; ZHANG et al., 2019). Neste sentido, Wang et al. (2012) carregaram soro o antígeno soro albumina bovina (BSA) em nanopartículas de sílica mesoporosa (MSN) com diferentes tamanhos de partícula (130 nm, 450 nm e 1-2 $\mu$ m) e a administração de MSN-BSA por via oral à camundongos promoveu desenvolvimento de resposta imune produzindo IgG1 e IgG2, contribuindo para as pesquisas sobre a aplicação da SBA-15 como adjuvante para vacinação por via oral. Outro trabalho observou efeito semelhante quando administrado SBA-15, contendo antígeno específico de *Mycoplasma hyopneumoniae* por via oral em porcos. A administração oral foi capaz de produzir resposta imune específica para a bactéria, sendo observado aumento de anticorpos apenas nos animais que receberam a vacina por via oral (MECHLER-DREIBI et al., 2021b). Ainda, o tratamento adjuvante mostrou que camundongos imunizados pela via oral com as partículas purificadas da proteína viral HbsAg, o principal componente da vacina contra hepatite B, conjugado em SBA-15 apresentaram aumento na resposta imune, reportando aumento nos títulos de IgA e IgG específicas para o vírus (SCARAMUZZI et al., 2011).

Quanto a toxicidade associada a SBA-15, um estudo que administrou por via oral 40 mg/kg de sílica mesoporosa de área superficial em nanoescala, demonstrou rápida excreção nas fezes e urina. Nenhuma anormalidade histológica foi observada quando

avaliadas a histologia do fígado, baço, pulmões e coração. No entanto, foram observados efeitos tóxicos aos rins, apresentando necrose tubular renal e hemorragia e congestão vascular no interstício renal para todos os camundongos tratados nanopartículas mesoporosas. Vale ressaltar que nanopartículas mesoporosas têm maior absorção pela mucosa intestinal e conseqüentemente maior excreção renal, podendo ultrapassar o limite de filtração glomerular e causar lesões renais (LI et al., 2015). Sugere-se então que a SBA-15 possa ser absorvida pela mucosa intestinal de acordo com suas características físicas, no entanto por apresentar grande área superficial, pode ser majoritariamente excretada nas fezes (ZHAO et al., 1998b). Além disso, um estudo de toxicidade intestinal utilizando diferentes tipos de sílica mesoporosa tratadas oralmente, demonstrou que a SBA-15 não gerou toxicidade intestinal na dose de 50 mg/kg administrados por 7 dias por via oral (YU et al., 2021). Apesar do tratamento por via oral ser promissor e seguro, outras vias de administração como a subcutânea e intravenosa necessitam de mais estudos para aferir a segurança e efeito. Choi et al. (2015) demonstrou que a SBA-15 aplicada via subcutânea observou a formação de nódulos na região dorsal de camundongos. Esse resultado foi associado à baixa absorção do material por essa via.

Devido as suas características físicas e químicas, a SBA-15 apresenta potencial promissor para o desenvolvimento de sistema de entrega controlado e cólon específico, permitindo o carreamento de fármacos e proteínas de alto peso molecular. Do exposto acima fica evidente que a implementação de novas tecnologias e estudos experimentais são necessários para a implementação de abordagens terapêuticas inovadora, de forma que o planejamento cuidadoso desses sistemas de entrega em relação ao alvo e a via de administração possa resolver alguns dos problemas enfrentados pelas novas classes de moléculas ativas, e otimizando o tratamento de diversas doenças, em especial as DIIs.

### **Métodos alternativos para o estudo de DIIs**

Apesar da aplicação de diversas abordagens terapêuticas no tratamento das DIIs, muitas delas enfrentam desafios que resultam frequentemente em falhas terapêuticas. É notável que diversos fatores podem estar associados a falhas terapêuticas, e muitos deles poderiam ser identificados por meio de estudos prévios. De fato, entre 40 a 50% dos medicamentos falham durante a fase clínica devido à

ausência de efeito comprovado das substâncias. Nesse contexto, para aprimorar as terapias existentes e não apenas introduzir novas moléculas terapêuticas, torna-se crucial a busca por métodos de análise inovadores. Esses métodos visam avaliar tanto a segurança quanto a eficácia dessas abordagens em ensaios clínicos. A implementação de análises mais robustas e estudos aprofundados pode contribuir não apenas para a compreensão das causas das falhas terapêuticas, mas também para otimizar o desenvolvimento de tratamentos mais eficazes e personalizados para pacientes com diferentes tipos de doenças crônicas como o câncer e até mesmo as DIIs (KIRIIRI; NJOGU; MWANGI, 2020; SUN et al., 2022; TEBON et al., 2023).

Os modelos tradicionais de estudos *in vivo* das DIIs compreendem, principalmente, a indução química da doença em modelos de DSS ou ácido 2,4,6-trinitrobenzeno sulfônico (TNBS), além do desenvolvimento de animais geneticamente modificados com deficiências no sistema imune inato e sistema e adaptativo (BAYDI et al., 2021; CHASSAING et al., 2014; NEURATH; FUSS; STROBER, 2000). Estes modelos são vantajosos no sentido de replicar o sistema fisiológico e todas as interações que ocorrem durante a doença, sendo indispensáveis para o estudo destas doenças. Porém, a indução química da colite apresenta limitações como a heterogeneidade no desenvolvimento da doença, que se desenvolve de forma diferente daquela observada em humanos, além do fato de as DIIs serem doenças com mecanismos celulares e moleculares muitas vezes específicos da espécie, características que dificultam a associação desses resultados para humanos (GOULD; JUNTILA; DE SAUVAGE, 2015). Além disso, o uso de células humanas imortalizadas, como Caco-2, T84 e HT-29, tem sido amplamente utilizado para compreender a permeabilidade intestinal e compreender os mecanismos de reparação tecidual, mas são limitadas quanto às interações complexas que ocorrem *in vivo* (JIMINEZ et al., 2015; O'CONNELL; WINTER; AHERNE, 2021; SOLLID; JOHANSEN, 2008).

No cenário atual, o desenvolvimento de culturas celulares tridimensionais (3D) utilizando células-tronco adultas ou progenitoras para recriar tecidos *in vitro* surge como uma alternativa para superar as limitações das culturas 2D. Denominadas organoides, essas estruturas teciduais compartilham características semelhantes às dos órgãos, destacando-se como uma ferramenta valiosa para contornar as restrições dos modelos *in vitro* de células em monocamada. Tornam-se, assim, uma opção eficaz

para estudos de toxicidade, modelos de doenças e avanços na medicina personalizada, reproduzindo as funções estruturais, funcionais e genóticas de órgãos específicos (JENSEN; TENG, 2020; KIM; KOO; KNOBLICH, 2020; RODRIGUEZ-GARCIA et al., 2020).

Os organoides podem originar-se de dois tipos de células com capacidade de diferenciação e auto-organização que refletem a origem do órgão: (1) células-tronco embrionárias pluripotentes e (2) células-tronco adultas (CLEVERS, 2016). A formação dessas estruturas baseia-se no rearranjo estrutural e morfogênico, resultante da interação física entre diferentes tipos celulares, considerando características como adesão, tensão, motilidade e contratilidade célula-célula (SASAI, 2013). A compreensão da sinalização celular que ocorre *in vivo* nas criptas intestinais tornou possível o desenvolvimento dos organoides. O gradiente de substâncias responsáveis pelas fases de proliferação e diferenciação celular é controlado pela adição de inibidores ou componentes necessários para a manutenção das células-tronco (CLEVERS, 2016).

A evolução dos diversos tipos de organoides proporciona uma compreensão mais aprofundada da organogênese e da fisiopatologia de diversas doenças. Na abordagem das DIIs, por exemplo, a criação de "mini-órgãos" tem se destacado como um modelo mais acessível em comparação com o uso de animais. Além disso, essa abordagem possibilita discernir a contribuição relativa de diferentes componentes teciduais para processos morfogênicos complexos, oferecendo uma visão mais precisa das características específicas da doença (CALÀ et al., 2023; KRETZSCHMAR; CLEVERS, 2016; LI et al., 2014; NADAULD et al., 2014).

Organoides intestinais em 3D são capazes de manter as características e funções da célula original por longos períodos, mesmo em cultura, sendo capazes de sobreviverem por períodos mais prolongados *in vitro*, o que representa uma vantagem significativa em comparação com a capacidade limitada de propagação das células primárias (DOTTI et al., 2017; WANG et al., 2021). Essa abordagem inovadora baseada em células-tronco resulta no desenvolvimento de organoides 3D, tanto murinos quanto humanos. A diferenciação *in vitro* das células-tronco Lgr5+ possibilita a diferenciação em todos os tipos de células epiteliais do cólon, assemelhando-se ao intestino (CLEVERS, 2016; SATO et al., 2009). Dadas essas características, o modelo de organoides intestinais 3D permite a investigação do impacto de agentes tóxicos ambientais na integridade da barreira intestinal (SHARMA et al., 2021), explorar a

patogênese de patógenos intestinais (SAYED et al., 2020a, 2020b), e avaliar a eficácia de intervenções terapêuticas potenciais contra a DIIs (SAHOO et al., 2021).

A utilização de organoides na modelagem de doenças tem revelado *insights* cruciais em diversos aspectos, incluindo a importância da microbiota intestinal, interações do sistema imunológico e o desenvolvimento de tratamentos personalizados. No contexto da DII, onde os tratamentos visam predominantemente a regulação da resposta imune, o desenvolvimento de organoides a partir de células obtidas por biópsias de pacientes se mostra uma ferramenta valiosa de triagem (SARVESTANI et al., 2021), permitindo avaliar de forma mais confiável e específica a abordagem farmacológica para cada paciente (ANGUS et al., 2020; BAR-EPHRAIM; KRETZSCHMAR; CLEVERS, 2020; O'CONNELL; WINTER; AHERNE, 2021). Estudos comparativos entre organoides de pacientes com DII e saudáveis destacaram características distintas nos pacientes com a doença, como fenótipo inflamatório, aumento da morte celular e alterações nas junções celulares, que responderam aos tratamentos comuns, como anti-TNF e glicocorticoides (D'ALDEBERT et al., 2020).

Essa abordagem avançada não apenas amplia nossa compreensão das interações entre agentes tóxicos, patógenos e a barreira intestinal, mas também oferece uma plataforma promissora para o desenvolvimento de intervenções terapêuticas específicas para DII. Ao prolongar a viabilidade *in vitro* dos organoides e ao utilizar o modelo de “intestino em placa de cultura”, conseguimos simular de maneira mais precisa o ambiente colônico humano, proporcionando um contexto relevante para estudos de toxicidade, investigação de patógenos e pesquisa terapêutica direcionada à DII. Este avanço, portanto, representa um passo significativo na melhoria da modelagem *in vitro* e no desenvolvimento de estratégias terapêuticas mais eficazes para doenças gastrointestinais (BASAK et al., 2017; SATO et al., 2011; TIAN et al., 2023).

# *Objetivos*

O objetivo desse projeto foi formular e realizar a caracterização físico-química de novas estratégias terapêuticas sobre a colite experimental induzida pelo DSS utilizando a AnxA1 e seu peptídeo mimético Ac2-26, e avaliar a sua eficácia por diferentes vias de administração em camundongos.

*Materiais e  
métodos*

## Síntese e obtenção da MLNC contendo AnxA1

A síntese das nanocapsulas foi realizada com o auxílio do grupo de pesquisa da Profa. Dra. Adriana Raffin Pohlmann, do Instituto de Química, e da Profa. Dra. Silvia Stanisçuaski Guterres, da Faculdade de Farmácia, ambas da Universidade Federal do Rio Grande do Sul, além do auxílio do aluno de doutorado Matheus de Castro Leão, aluno da Profa. Inar Castro, do Programa de Ciências dos Alimentos da Faculdade de Ciências Farmacêuticas da USP.

As suspensões de LNC utilizadas neste trabalho foram preparadas conforme método já descrito, chamado deposição interfacial de polímero pré-formado (JÄGER et al., 2009; MÜLLER C.R et al., 2001; VENTURINI et al., 2011). A fase orgânica foi preparada pela dissolução do componente oleoso, um triglicerídeo de cadeia média (TCM), a lecitina, o monoestearato de sorbitano e a blenda polimérica de poli (epsiloncaprolactona) (PCL) em um volume de 25 mL de acetona e 5 mL de éter. Esta foi suspensão mantida sob agitação e aquecimento a 40°C por 2 horas. Em um frasco separado, o polissorbato 80 (tensoativo de caráter hidrofílico) foi disperso em água ultrapura, permanecendo sob agitação, a 40°C por 2 horas (Tabela 1). Após a completa dissolução dos componentes de ambas as fases, a orgânica foi injetada na fase aquosa utilizando-se um funil. A suspensão resultante foi mantida sob agitação moderada (125 rpm) por 10 minutos, permanecendo sob agitação, a 40°C. A suspensão foi concentrada a um volume final de 10 mL em evaporador rotatório, para eliminação dos solventes orgânicos e concentração da suspensão.

**Tabela 1.** Componentes da fase orgânica e fase aquosa da LNC.

Fase orgânica		Fase aquosa	
Matéria-prima	Volume	Matéria-prima	Volume
PCL	0,100 g	Água MilliQ®	60mL
TCM	120 µL	PS80	0,080g
Acetona	25 mL		
Lecitina	0,090 g		
Etanol	5 mL		
Monoesterato de sorbitano	0,040 g		

Fonte: o autor.

Para revestir a LNC, uma solução de quitosana (7 mg/mL) foi preparada por meio da dissolução do polissacarídeo em uma solução aquosa contendo 1% de ácido acético. Uma proporção de 10% desta solução foi adicionada por gotejamento à solução de LNC, sendo preparada comumente uma solução contendo 4,5 mL de LNC e 0,5 mL de quitosana. A solução foi mantida por 2 horas em agitação, a temperatura ambiente. Ao final deste período obteve-se a MLNC.

Para a funcionalização da MLNC com AnxA1 foi necessária a complexação de íons zinco ( $Zn^{2+}$ ) na MLNC. Para tanto, uma solução de acetato de zinco (25  $\mu$ g/mL diluídos com água MilliQ®) foi preparada e incorporada ao complexo da MLNC. Em seguida, a AnxA1 foi incorporada à estrutura polimérica da MLNC na concentração de 200  $\mu$ g/mL (Figura 5). A AnxA1 recombinante (rAnxA1) foi cedida pelo Dr. Chris Reutlelinsperger da Universidade de Maastrich, Holanda.

**Figura 5.** Representação gráfica do rearranjo estrutural de LNC, MLNC e MLNC-AnxA1

## ***Análise físico-química das nanocapsulas***

### *Espectroscopia de correlação de fótons potencial zeta*

A curva de distribuição de tamanho de partícula, diâmetro hidrodinâmico médio (DLS) e índice de polidispersão (PDI) de todas as formulações foram determinados por espectroscopia de correlação de fótons (PCS), usando um Zetasizer® Nano ZS (Malvern, Reino Unido). Cada amostra foi diluída (500x) em água ultrapura (MilliQ®) filtrada (Millipore®, 0,45 µm), conforme descrito por Cé et al. (2016).

### *Potencial zeta*

O potencial Zeta de todas as formulações foi determinado a partir da mobilidade eletroforética determinada por espalhamento de luz eletroforética em Zetasizer Nano ZS (Malvern, Reino Unido). Cada amostra foi diluída (500x) em solução aquosa filtrada (Millipore®, 0,45 µm) de NaCl (10 mmol/L) e o resultado expresso em milivolt (mV).

### *Análise de rastreamento de NPs (NTA)*

A medição da distribuição de tamanho e a concentração das formulações foram determinadas por NTA (NanoSight LM10 & NTA 2.0 Analytical Software, NanoSight Ltd). Foram obtidas informações visuais da luz espalhada pela partícula em solução. As imagens de vídeo de luz espalhada pela partícula em movimento browniano foram seguidas em uma câmera vídeo CCD em tempo real. As formulações foram diluídas 20.000 vezes e cada videoclipe foi capturado por 60 segundos. O software analítico NTA 2.0 (NanoSight ®) foi usado para os cálculos. A análise foi realizada pela Dra. Aline Alves em colaboração com o grupo da Profas. Adriana Pohlmann e Silvia Guterres da Universidade Federal do Rio Grande do Sul.

### *Análise de pH*

O valor de pH das formulações foi medido em potenciômetro (DM-22, Digimed, Brasil), calibrado com tampão fosfato (pH 4,01 e pH 6,86) em cada amostra sem diluição prévia. As medidas foram obtidas com sensibilidade  $\geq 99\%$

### *Microscopia eletrônica de transmissão (MET)*

As nanoformulações foram submetidas à análise morfológica em microscópio eletrônico de transmissão operando a 80kV. Amostras de nanocápsulas (100 µL) foram diluídas em água (1:10, v/v) e 20 µL da diluição foram depositados em grades de cobre (300 mesh) revestidas com filmes de carbono. Em seguida, um contraste negativo (solução de acetato de uranila 2%) foi adicionado à grade e mantido em dessecador a vácuo por 24 horas. As fotomicrografias foram posteriormente realizadas por técnicos treinados. A análise foi realizada pela Dra. Aline Alves em colaboração com o grupo da Profas. Adriana Pohllmann e Silvia Guterres da Universidade Federal do Rio Grande do Sul.

#### *Quantificação de AnxA1 conjugada a MLNC*

O rendimento da complexação de AnxA1 na superfície da nanocápsula foi determinado por um método indireto. Para isolar a fração não ligada de AnxA1, as nanocápsulas vetorizadas foram colocadas em unidades de ultrafiltração-centrifugação (100 kDa; Merck KGaA) e centrifugadas a 1840 × g durante 5 min (Sigma® 1-14; SIGMA Laborzentrifugen GmbH, Alemanha). A fração não ligada de AnxA1 nas formulações foi quantificada por um método colorimétrico (QuantiPro™ BCA Assay Kit, Sigma-Aldrich, St. Louis, MO, EUA). De acordo com as instruções do fabricante, uma curva de calibração foi preparada usando diluições de BSA e AnxA1 (3 a 27 µg/mL). A absorbância do produto da reação foi registrada em um leitor de placas a 562 nm (Spectramax, Molecular Devices, Sunnyvale, CA, USA) onde o índice de correlação foi de 0,9917.

#### **Síntese e caracterização da SBA-15 contendo Ac2-26**

##### ***Obtenção da SBA-15-Ac2-26***

A micropartícula SBA-15 foi sintetizada no Instituto de Física da Universidade de São Paulo, Brasil, pelo pesquisador Luis Carlos Cides de acordo com trabalho anterior (MATOS et al., 2001). Para a síntese da SBA-15 foram utilizados 4 g de Pluronic P123 (PEO<sub>20</sub>PPO<sub>70</sub>PEO<sub>20</sub>) (BASF, Alemanha), o qual foi dissolvido em 122 g de solução de HCl 2M e mantido sob agitação magnética e mecânica por 1 hora.

Foram adicionados 8,6 g de tetraetilortossilicato (Sigma-Aldrich; St. Louis, EUA) e a solução foi mantida sob agitação por 24 horas. Após esse processo, a mistura foi submetida a tratamento hidrotérmico por 48 horas a 100 °C em autoclave, posteriormente lavada com água deionizada e seca em temperatura ambiente. O molde de polímero foi então removido por calcinação a 540 °C em N<sub>2</sub> por 2 horas e ao ar por 4 horas.

O peptídeo A2-26 foi adquirido da empresa Proteinmax - São Paulo, Brasil. A incorporação de Ac2-26 resultou da dissolução do peptídeo em água MilliQ; em seguida foi realizada a mistura de SBA-15:Ac2-26 (1:1), onde 1 mg/mL de Ac2-26 foi adicionado a 1 mg de SBA-15. A mistura foi seca em estufa a 35°C até secagem completa. Para o revestimento com Eudragit® L30-D55 (Evonik Industries AG - Rellinghauser Straße – Essen Germany) foi adicionada uma proporção de 1:2 de SBA-15-Ac2-26 e Eudragit®. O material foi seco em estufa a 35°C por 4 horas e depois armazenado em congelador a -20°C.

#### *Caracterização por DLS do peptídeo Ac2-26*

A medição do espalhamento dinâmico de luz para analisar o tamanho de partícula foi realizada à temperatura ambiente, utilizando o equipamento Brookhaven DM-5000 (Brookhaven Instruments, NY, EUA) com comprimento de onda de 635 nm. A análise dos dados foi realizada utilizando o software BIC fornecido com o equipamento. A amostra foi diluída para 1 mg/mL para mitigar a influência da interação interpartículas no coeficiente de difusão das partículas e, conseqüentemente, nos dados obtidos. Estas análises foram realizadas pelo grupo da Profa. Marcia Fantini, do Instituto de Física da Universidade de São Paulo.

#### *Espalhamento de raios X de pequeno ângulo - Small-angle X-ray Scattering (SAXS)*

A análise por SAXS e adsorção de nitrogênio foram realizadas no Instituto de Física da USP pelos pesquisadores e Pedro Leonidas Oseliero Filho e Luis Carlos Cides. A análise por SAXS foi realizada em um instrumento Nanostar (Bruker, Buffalo, EUA) equipado com um sistema microfoco Genix 3D (Xenocs, Massachusetts, EUA) e um detector Pilatus 300k (Dectris, Baden Suíça). A distância amostra-detector foi de ~667 mm, o que forneceu uma faixa efetiva do módulo do vetor de momento de transferência,  $q = 4\pi\sin(\theta)/\lambda$  (onde  $2\theta$  é o ângulo de espalhamento e  $\lambda = 1,5418 \text{ \AA}$  é

o X- comprimento de onda do raio), de 0,015 a 0,30 Å<sup>-1</sup>. Para os experimentos, a água deionizada (utilizada no preparo da amostra) e a mesma amostra dos ensaios DLS foram medidas, em temperatura ambiente, em capilar de quartzo reutilizável com 1,5 mm de diâmetro montado em caixas de aço inoxidável. Amostras em pó de SBA-15 e SBA-15 adicionado ao peptídeo foram colocadas em um porta-amostras entre duas folhas de mica. Um conjunto de folhas de mica também foi medido para fins de correção de *background*. O tratamento dos dados, que inclui integração azimutal, subtração de fundo e normalização de escala absoluta (para a amostra líquida), foi realizado utilizando o software XSACT fornecido pela Xenocs.

A determinação da isoterma de adsorção de nitrogênio (*Nitrogen Adsorption Isotherm*, NAI) foram obtidas no equipamento ASAP2020 (Micromeritics®, Atlanta, EUA) utilizando gás nitrogênio. Nessa técnica, nitrogênio é adsorvido pelos poros (ou seja, o gás entra e preenche os poros) e posteriormente dessorvido (ou seja, o gás sai dos poros) em temperatura constante. Estas análises foram realizadas pelo grupo da Profa. Marcia Fantini, do Instituto de Física da Universidade de Universidade de São Paulo.

### *Conjugação de SBA-15 e Ac2-26 a corantes fluorescentes*

Para aplicação de SBA-15 e Ac2-26 em ensaios de rastreo da micropartícula/peptídeo *in vivo* e internalização celular *in vitro*, a micropartícula SBA-15 e o peptídeo Ac2-26 foram funcionalizados com fluoróforos. A SBA-15 foi funcionalizada previamente com 3-aminopropiltrimetoxissilano (APTES), o que permitiu a ligação de grupos amina presentes na estrutura do fluoróforo isotiocianato de fluoresceína (FITC)(Sigma-Aldrich; St. Louis, EUA). A conjugação foi realizada conforme protocolo descrito por Appiah-Ntiamoah et al. (2015). Após marcação, a SBA-15-FITC foi analisada por medidas SAXS para confirmação da conjugação do fluoróforo. A SBA-15-FITC foi então armazenada em congelador a -20 °C.

A conjugação do peptídeo foi realizada em colaboração com o laboratório do Professor Marco Antônio Stephano, FCF, USP. O peptídeo Ac2-26 foi conjugado com o corante Cianina 5.5 (Cy5.5 - Lumiprobe Corporation, Hunt Valley, USA). Ac2-26 foi dissolvido em tampão salina de fosfato (PBS) (pH de 7,4) para atingir uma concentração de 1,0 mg/mL. Simultaneamente, 1 mg de corante Cy5.5 foi dissolvido

em 1 mL de DMSO 1 mM. O peptídeo e o corante Cy5.5 foram misturados na proporção molar de 1:10, e qualquer excesso de corante foi removido por diálise usando uma membrana de 10 mm com ponto de corte de 500 Da. O peptídeo marcado com Cy5 foi purificado com Sephadex G-25 e depois liofilizado. A análise por espectrofotometria a 215 nm (Shimadzu Scientific, Marlborough, EUA) confirmou o sucesso do processo de rotulagem. O rendimento do peptídeo marcado com Cy5.5 foi de dez frascos, cada um contendo 450 µg.

#### *Estabilidade de Eudragit-SBA-15-Ac2-26*

Foram preparadas diferentes soluções mimetizando o pH estomacal e intestinal. A solução gástrica foi preparada utilizando NaCl (0,2 g) e HCl (0,7 mL) e o volume completado para 100 mL e o pH ajustado para 1,2. Já a solução intestinal foi preparada com KH<sub>2</sub>PO<sub>4</sub> (0,68 g), NaOH (2N – 7,7 mL), o volume completado para 100 mL de H<sub>2</sub>O e o pH ajustado para 6,8 (Mariano-Neto 2014). A solução de Eud-SBA-15-Ac2-26 (5 mg) foi misturada à solução tampão e a quantificação da concentração de peptídeo liberado foi analisada em diferentes tempos. Para quantificar o peptídeo liberado foi utilizado O QuantiPro™ BCA Assay Kit (Sigma-Aldrich) capaz de detectar proteínas nas concentrações de 0,5 to 30 µg/mL.

## **Experimentação animal**

### ***Animais***

Foram utilizados camundongos C57Bl/6, machos com 8 a 10 semanas e pesando de 20 a 25 g. Os animais foram fornecidos pelo Biotério da Universidade Federal do Estado de São Paulo (UNIFESP) e mantidos em ciclo de 12 horas claro/escuro, temperatura de 20 a 25°C, com água e ração *ad libitum*. A execução do presente estudo foi aprovada pela Comissão de Ética no Uso de Animais da Faculdade de Ciências Farmacêuticas da Universidade de São Paulo. CEUA/FCF/USP - Protocolo nº 598 - MLNC-AnxA1 (Anexo 1 e 2). CEUA/FCF/USP - Protocolo nº 653 – SBA-15-Ac2-26 (Anexo 3).

### Colite experimental

A colite experimental foi induzida pela ingestão de dextran sulfato de sódio (DSS - MW 40,000, Dextran Products Limited, Ontario, Canadá) veiculado na água dos animais durante 6 dias, sendo trocado a cada dois dias para que os animais recebessem doses constantes. Os tratamentos foram veiculados aos animais do 6º dia ao 9º dia de experimento (Figura 6). No 10º dia de experimento, os animais foram anestesiados e o sangue coletado pela aorta abdominal após abertura ventral. Em seguida, o cólon foi removido a partir da junção ileocecal até a proximidade do ânus, lavado com solução isotônica e avaliado macroscopicamente (peso e comprimento). Finalmente, o órgão foi fragmentado para análises histológicas (cólon distal), celulares (cólon médio) e de citocinas pró e anti-inflamatórias (cólon proximal). Ainda, parâmetros clínicos (peso corpóreo, diarreia e sangramento retal) foram avaliados diariamente (Dia 0 ao dia 10), para análise da evolução da doença e o Índice de Atividade da Doença (IAD) calculado a partir da soma dos parâmetros avaliados.

**Figura 6.** Cronograma de indução da colite experimental e tratamentos

No dia 0 foram realizadas as coletas de fezes e aferição do peso, e o iniciou da indução da doença pela adição de 2% de DSS à água dos animais. A coleta de fezes e aferição do peso foi realizada diariamente durante os 10 dias de experimento. O DSS foi removido no 6º dia de experimentação e os tratamentos foram iniciados no mesmo dia, seguindo-se até o 9º dia. No 10º dia os animais foram eutanasiados. Fonte: o autor.

### Tratamentos

#### MLNC-AnxA1

Os tratamentos com MLNC-AxA1 foram administrados via oral, intravenoso e intraperitoneal. No tratamento por via oral, os animais foram tratados com AnxA1 (100 µg/mL) ou MLNC-AnxA1 (100 µg/mL –  $3,1 \times 10^{12}$  partículas) em um volume final de 250

$\mu\text{L}$ . O tratamento intravenoso foi realizado com AnxA1 (10  $\mu\text{g}/\text{mL}$ ), MLNC ( $7,5 \times 10^{10}$  partículas/ $\text{mL}$ ) ou MLNC-AnxA1 (10  $\mu\text{g}/\text{mL}$  –  $7,5 \times 10^{10}$  partículas/ $\text{mL}$ ) em um volume final de 50  $\mu\text{L}$ . O tratamento intraperitoneal foi conduzido com AnxA1 (12,5  $\mu\text{g}/\text{mL}$ ), MLNC ( $9,6 \times 10^{11}$  partículas/ $\text{mL}$ ) ou MLNC-AnxA1 (12,5  $\mu\text{g}/\text{mL}$  –  $9,6 \times 10^{11}$  partículas/ $\text{mL}$ ) em um volume final de 200  $\mu\text{L}$ . Os grupos controle, que receberam apenas DSS 2%, receberam os volumes equivalente a cada via de administração de água MilliQ (veículo utilizado na diluição e preparação dos outros grupos).

#### *SBA-15-Ac2-26*

Para o tratamento com SBA-15-Ac2-26, os animais foram divididos em quatro grupos: Naive, DSS, DSS+SBA-15-Eudragit (200  $\mu\text{g}$ ) e DSS+SBA-15-Ac2.26-Eudragit-SBA-15-Ac2.26 (200  $\mu\text{g}/200 \mu\text{g}$ ). Os tratamentos foram preparados em PBS pH 5 em um volume final de 400  $\mu\text{L}/\text{animal}$ . O grupo DSS foi tratado com 400  $\mu\text{L}$  de PBS pH 5. Os tratamentos foram realizados diariamente por via oral, entre os dias 6 e 9.

#### *Processamento histológico*

Fragmentos coletados da parte distal do cólon foram fixados por 24 horas de incubação em paraformaldeído a 4%. Posteriormente, foram desidratados em etanol graduado 100%, 90% e 70%, clarificados em xilol e embebidos em parafina para análises histopatológicas e imuno-histoquímicas de acordo com nossos manuscritos anteriores (De Paula Silva 2016, 2021; Da Rocha 2020).

A análise histopatológica foi realizada em cortes de 4  $\mu\text{m}$ . As amostras foram coradas com solução de hematoxilina e eosina e analisadas com objetiva de alto aumento (40 $\times$ ) em AxioCam acoplada a microscópio Zeiss (Carl Zeiss, Jena, Alemanha). A análise do escore histopatológico foi realizada de forma cega por dois analistas conhecedores das características do tecido intestinal. O escore considerou: edema tecidual, displasia/histoarquitetura alterada, edema de cripta, infiltrados inflamatórios e ulcerações. A análise de escore histológico foi adaptada de de Paula-Silva, (2020) e (Geboes et al. (2000)). Foram considerados valores de 0 a 4 onde: 0 = ausência total; 1 = discreta; 2 = moderada; 3 = intensa; 4 = total descaracterização do tecido. Dez fotos foram capturadas de cada corte histológico usando uma objetiva de alto aumento de 20 $\times$  e as pontuações foram avaliadas em uma escala que varia de 0 a 4.

### *Imunohistoquímica*

As secções de cólon foram desparafinizados, hidratados e incubados com tampão citrato de sódio (pH 6,0) a 96°C por 30 minutos. A atividade da peroxidase endógena foi bloqueada com peróxido de hidrogênio a 3%, lavado três vezes após cada 10 minutos de incubação. Em seguida, o bloqueio de sítios de ligação inespecíficos foi realizado com BSA, 1% diluído em tampão salina Tris (TBS) por 1 hora. As secções obtidas foram incubadas com anticorpos descritos na Tabela 2, e mantidos a 4°C. No dia seguinte, as secções foram lavadas e incubadas com anticorpo secundário conjugados com HRP (Abcam, Cambridge, Reino Unido) (1 hora, em temperatura ambiente, ao abrigo da luz) e detectados com 3,3'-diaminobenzidina (DAB - Dako Omnis, Agilent, Santa Clara, California, EUA). Por fim, as secções foram contrastadas com hematoxilina e as lâminas montadas. A análise de marcação dos anticorpos foi realizada utilizando o microscópio Imer. A2 Zeiss (Carl Zeiss, Jena, Alemanha). A quantificação dos núcleos proliferativos, células MUC2+ e CD163+ foram avaliada pelas fotografias utilizando uma objetiva de 40× em dez campos da camada mucosa e quantificados para cada campo avaliado.

A porcentagem de área marcada de Claudina-1 e ZO-1 e a quantificação de células positivas para PCNA, Ki67, MUC-2 e CD163 foram obtidas utilizando o *software* ImageJ. Os resultados foram expressos como média ± erro padrão da média (EPM) de porcentagem da área marcada.

**Tabela 2.** Anticorpos utilizados para imunohistoquímica

<b>Anticorpos</b>	<b>Diluição</b>	<b>Fabricante</b>	<b>Experimento</b>
Claudina 1	1:50	Abcam	MLNC/SBA
ZO-1	1:50	Abcam	MLNC
PCNA	1:10	Santa Cruz	MLNC/SBA
Ki67	1:100	Abcam	MLNC
MUC-2	1:100	Invitrogen	SBA
CD163	1:100	Bioss Antibodies Inc	SBA

Fonte: o autor

### *Análise celular da lâmina própria*

Após a coleta de material dos animais, fragmentos do cólon foram coletados e processados para extração das células de lâmina própria, conforme descrito previamente por Sena et al. (2015) e adaptado em nosso laboratório. Tecidos

adjacentes foram retirados e as amostras foram imersas em 5 mL de solução de PBS-gentamicina, em gelo. O conteúdo dos fragmentos intestinais foi aberto longitudinalmente para remoção do conteúdo fecal e colocado em tubo de 15 mL contendo solução de Hanks (isenta de  $\text{Ca}^{2+}$  e  $\text{Mg}^{2+}$ ) e mantidas em gelo sob agitação durante 15 minutos, para remoção das células epiteliais de mucosa. Esse processo de lavagem foi repetido duas vezes e a solução de Hanks trocada entre as lavagens. O tecido foi lavado em PBS para e incubado com 2 mL de solução de colagenase II e IV, a 37°C, sob agitação, por 20 minutos, sob agitação a cada 5 minutos. Em seguida, foram adicionados 2 mL de PBS contendo 10% de soro fetal bovino (SFB) em cada tubo, e as células extraídas separadas do restante do tecido com o auxílio de um *cell strainer*. Essa solução foi centrifugada a 1200 g, por 5 min, e o sobrenadante foi descartado. Por fim, as células foram ressuspensas em 1 mL de PBS + 10% de SFB e mantido em gelo para início imediato da técnica de citometria de fluxo.

Células isoladas da lâmina própria foram contadas em câmara de Neubauer e a concentração de  $1 \times 10^6$  células foram utilizadas para análise de citometria de fluxo. As amostras foram incubadas em tampão FACS contendo os diferentes anticorpos (Tabela 3) anticorpos Ly6G (granulócitos), F4/80 (células apresentadoras de antígeno) e CD4 (linfócitos T). As concentrações e marcações foram feitas de acordo com as instruções do fabricante e analisadas em citômetro de fluxo BD Accuri™ C6. Para as análises, 50.000 células foram detectadas e quantificadas por porcentagem.

**Tabela 3.** Anticorpos conjugados com fluoróforos utilizados para citometria de fluxo

Anticorpos	Diluição	Fabricante	Fluoróforo
CD80	1:50	BD Bioscience	PE
CD206	1:25	BD Bioscience	FITC
F4/80	1:100	BD Bioscience	PerCP-Cy5.5
Ly6G	1:100	BD Bioscience	APC

CD: cluster of differentiation; PE: phycoerythrin FITC: fluorescein isothiocyanate; PerCP-Cy5.5: PerCP-Cyanine5.5; APC: Allophycocyanin.

### ***Avaliação in vivo e ex vivo de SBA-15 e Ac2-26 no trato gastrointestinal***

O rastreamento da SBA-15 no trato gastrointestinal (TGI) foi avaliado por SBA-15-FITC revestido com Eudragit. Eudragit-FITC-SBA-15 (400 µg/400 µL) foi administrado

oralmente a camundongos saudáveis. Os animais foram eutanasiados 6 ou 18 horas após o tratamento para retirada do TGI. A distribuição de Eudragit-SBA15-Ac2-26Cy5.5 foi analisada após 3 horas e 8 horas e o TGI analisado *ex vivo* nos mesmos intervalos de tempo.

As imagens de fluorescência *ex vivo* foram adquiridas utilizando o equipamento IVIS® Lumina LT Series III (Xenogen Corp., Alameda, CA, EUA), com as seguintes parâmetros para obtenção das imagens: excitação/emissão 465/520, tempo de exposição automático, F/stop 4 e binning de 4. Para análise de intensidade de fluorescência selecionamos uma região de interesse e normalizamos pelas áreas correspondentes. Os sinais adquiridos foram analisados utilizando o Living Image® Software versão 4.7.2 (PerkinElmer®) em unidades de fótons/s. As análises foram realizadas no laboratório do Professor Lionel Fernel Gamarra, localizado no Instituto Israelita de Ensino e Pesquisa Albert Einstein.

### **Análises *in vitro***

Macrófagos murinos da linhagem celular Raw 267.7 e células Caco-2 (células epiteliais derivadas de intestino humano) foram obtidos do banco de célula do Rio de Janeiro (BCRJ®) e foram utilizados para realização dos ensaios de citotoxicidade pelo ensaio de redução do (3-(4,5-Dimethylthiazol-2-yl)-2,5-DiphenyltetrazoliumBr) (MTT), morte e captação celular. A linhagem celular de macrófagos de camundongo J774A.1 (ATCC®; Washington DC, EUA) também foi utilizada para ensaios de captação celular. As células Raw 264.7 e J774A.1 foram mantidas com meio de cultivo celular *Dulbecco's Modified Eagle Medium (DMEM)* (Gibco™, Estados Unidos) suplementado com 10% de SFB (Gibco™) e 1 mM de piruvato em estufa a 37°C com 5% de CO<sup>2</sup>. Células Caco-2 foram cultivadas com meio *Dulbecco's Modified Eagle Medium (DMEM)* (Gibco™) suplementado com 20% de SFB (Gibco™). Para realização dos experimentos foram utilizadas as passagens celulares 8 a 15.

### **Ensaio de citotoxicidade por MTT**

As células Raw 264.7 foram plaqueadas (1x10<sup>4</sup>) em microplacas de 96 poços e mantidas a 37°C com 5% de CO<sub>2</sub>. Após 24 horas, os tratamentos foram realizados de acordo com os parâmetros apresentados nas Tabelas 4 e 5, e analisados após 24 e

48 horas de incubação. Como controle positivo de citotoxicidade foi empregado dimetilsulfóxido (DMSO) a 10%. O crescimento celular foi revelado pelo ensaio de MTT. Foram adicionados 10 µL de MTT (5 mg/mL) por poço e a placa mantida por 3 horas em estufa a 37°C e 5% CO<sub>2</sub>. Ao término desse período, o sobrenadante foi retirado e adicionados 100 µL de DMSO para a dissolução dos cristais de formazan formados pela redução do MTT. A densidade óptica (DO) de cada poço foi determinada em espectrofotômetro de microplacas em 570 nm (Asxys Expert 34 Plus, Microplate Reader G020 150, Eugendorf, Salzburg, ÁUSTRIA).

Os resultados em densidade óptica (DO) realizados em triplicata foram analisados empregando como indicador a porcentagem de viabilidade.

**Tabela 4.** Tratamentos de MLNC utilizados no ensaio de MTT

### **Viabilidade e morte celular**

Para analisar o tipo de morte gerada pelas MLNCs, células Raw 264.7 foram plaqueadas (5x10<sup>4</sup>) em placas de 24 poços e tratadas apenas com as concentrações que apresentaram maior redução da atividade mitocondrial no ensaio de MTT. Assim, os tratamentos consistiram em: AnxA1 (5000 ng), MLNC (150x10<sup>9</sup> partículas/mL) e MLNC-AnxA1 (77,5x10<sup>9</sup> e 150x10<sup>9</sup> partículas/mL). A morte celular foi aferida 24 e 48 após as incubações. Após os tratamentos, os sobrenadantes foram coletados e as

células que permaneceram aderidas foram removidas com a adição de solução de tripsina (Gibco™). Em seguida, foram centrifugadas a 1200g por 5 minutos, e ressuspensas em 200µL de tampão de ligação para a marcação com Anexina V conjugada com alofocianina (AnxV-APC) (diluição 1:20) e com 7-aminoactinomicina D (7-AAD) (diluição 1:200), ambos os anticorpos provenientes da BD Biosciences, Franklin Lakes, NJ, USA. As células foram incubadas por 30 minutos ao abrigo da luz e a temperatura ambiente. Em seguida, foi realizada a leitura por citometria de fluxo utilizando o equipamento Accuri C6 (BD Biosciences, Franklin Lakes, NJ, USA). Foram reportados 10 mil eventos e os resultados expressos em porcentagem (%). O grupo duplo negativo para marcação AnxV-7-AAD indica as células viáveis, marcação única com AnxV indica as células em apoptose, marcação única com 7-AAD indica as células em necrose e o grupo duplo positivo para AnxV-7-AAD indica grupo de células em apoptose tardia.

### ***Captação (Uptake) celular de MLNC e SBA-15-Ac2-26***

#### ***MLNC***

A análise da internalização de MLNCs por células Raw 264.7 foi realizada por microscopia hiperespectral de campo escuro (CytoViva®). Lamínulas livres de poeira e extra limpas (Nexterion Glass D # D263T; Schott) foram inseridas em placa de 6 poços. Na parte superior de cada lamínula, foram adicionados  $8 \times 10^4$  células/poço. Foram testadas apenas as maiores concentrações de MLNC ( $15 \times 10^9$  partículas/mL) e MLNC-AnxA1 ( $15 \times 10^9$  partículas/mL) que não alteraram a viabilidade celular, após incubação por 2 ou 24 horas. Um grupo controle foi mantido na presença de DMEM 10% SFB (não tratado [NT]). Em seguida, as células foram lavadas três vezes com solução de PBS suplementado com 5% de SFB. As lamínulas foram colocadas entre as lâminas livres de poeira e extra limpas (NexterionR Glass B; Schott, NY, EUA) e lamínulas (Nexterion Glass D # D263T; Schott). As células foram fotografadas usando o sistema de imagem CytoViva Ultra Resolution (CytoViva, Inc., AL, EUA) montado em um microscópio Olympus BX51 (ampliação de 1500 ×; Olympus Corporation, Tóquio, Japão), equipado com uma abertura numérica (NA) de fluorita 100 × óleo de íris de 0,6-1,30 objetiva e fonte de luz 75 W Xe. As imagens ópticas foram obtidas usando uma câmera Retiga EXi CCD de imagem Q (Olympus Corporation, PA, EUA) e câmera digital Dage XL CCD com software de processamento de imagem (DageR;

DAGE-MTI de MC, Inc., MI, EUA). As análises no microscópio foram conduzidas pelas Dra. Mayara Uchiyama, em colaboração com o grupo do Prof. Koiti Araki, do Instituto de Química da Universidade de São Paulo.

#### *Liberção in vitro de SBA-15-FITC e SBA-15-Ac2-26-Cy5.5*

O peptídeo Ac2-26 marcado com Cy5.5 foi incorporado a SBA-15 (seguindo o protocolo de incorporação) e empregado para testar a liberação do peptídeo nas células. A captação de SBA-15-Ac2-26Cy.5.5 e SBA-15-FITC foi medida por citometria de fluxo (BD, Accuri C6, Estados Unidos) em macrófagos de camundongo Raw 264.7 e células Caco-2. A presença do peptídeo Ac2-26-Cy5.5 foi analisada após 30 minutos, 2, 6 e 24 horas de incubação com SBA-15-Ac2-26Cy.5.5. Células Caco-2 foram utilizadas para medir a absorção de SBA-15-FITC após 4 e 24 horas de incubação. Após o período de tratamentos, as células foram recolhidas, lavadas duas vezes e ressuspendidas em PBS. Para quantificar a porcentagem de células positivas, foram coletados pelo menos 10.000 eventos. Os eventos foram coletados com a delimitação da população principal de células saudáveis, e o percentual foi definido em relação à condição não tratada.

Células J774A.1 foram semeadas em placas de 24 poços como descrito anteriormente. A citocalasina D (20  $\mu$ M) foi adicionada por 1 hora e removida antes do tratamento com SBA-15-FITC (10  $\mu$ g/mL). A captação celular foi verificada 4 e 24 horas após o tratamento, utilizando imagem celular (CELENA ® Logos Biosystem, EUA) e dez campos para cada condição experimental foram analisados. A porcentagem de células fagocíticas foi quantificada utilizando o software ImageJ.

#### ***Polarização de macrófagos derivados da medula-óssea pela MLNC-AnxA1***

O experimento foi realizado de acordo com o método previamente estabelecido por Ying et al. (2013). Inicialmente, camundongos C57Bl/6 foram anestesiados e eutanasiados para coleta dos fêmures esquerdo e direito para coleta do lavado medular, utilizando uma solução de PBS gelado contendo 2% de SFB. Em seguida o *pool* de medulas foi ressuspendido utilizando agulhas de 21G para dissociar as células e passá-las através de *cell strainer* de 70  $\mu$ m para remoção de outros tecidos. As células foram lavadas com solução de NH<sub>4</sub>Cl 0,8% e incubas em gelo para remoção das células vermelhas. Após centrifugação por 5 minutos, 500 x g a 4°C, as células

foram ressuspensas com meio BMDM, composto por meio IMDM (Iscove's Modified Dulbecco's Media) (Gibco™, Grand Island, New York, USA), 20% de sobrenadante de cultura de células L929, o qual é rico em fator de crescimento de monócitos (M-CSF) e 10% de SFB. As células foram contadas e plaqueadas na concentração de  $5 \times 10^5$  células/poço em placa de 24 poços e mantidas no meio BMDM por 7 dias para diferenciação celular. Após a padronização da diferenciação e obtenção de 90% de macrófagos diferenciados em cultura (dados não apresentados), as células foram tratadas com LPS de *Escherichia coli* O111:B4 (Sigma-Aldrich Co, Saint Louis, MO, USA) (100 ng/mL) e mantidas por 24 horas nessa condição para diferenciação em macrófagos M1. Após esse período foram realizados os tratamentos com dexametasona (500 ng/mL), AnxA1 (500 ng/mL), MLNC ( $15 \times 10^9$  partículas/mL) ou MLNC-AnxA1 ( $15 \times 10^9$  partículas/mL contendo 500 ng de AnxA1). Como controle positivo para polarização foi utilizado o corticóide dexametasona (500 ng/mL) (Aché Laboratórios Farmacêuticos S.A., Brasil). Após 48 horas de tratamentos, o sobrenadante foi retirado e armazenado para análise das citocinas interleucina-10 (IL-10) (BD OptEIA™ - BD, Becton Dickinson, New Jersey, EUA) e (TGFβ) (eBioscience™, California, EUA) por ensaio de ligação enzimática (Enzyme Linked Immuno Sorbent Assay – ELISA) de acordo com o manual de cada fabricante. A caracterização do fenótipo celular foi realizada pela marcação de anticorpos conjugados a fluoróforos previamente listados na Tabela 3. As células foram removidas e marcadas com os anticorpos F4/80, CD80 e CD206 para diferenciação de macrófagos M1 e M2. A análise foi realizada utilizando o equipamento Accuri C6 (BD Biosciences, Franklin Lakes, NJ, USA). A porcentagem de cada população celular foi reportada utilizando pelo menos dez mil eventos por amostra.

### ***Organoides intestinais***

#### *Produção e cultura de organoides de cólon murino*

Camundongos C57BL/6 foram mantidos de acordo com o protocolo *Institutional Animal Care and Use Committee* (IACUC) da Universidade de Massachusetts Lowell, Estados Unidos. Os organoides foram desenvolvidos a partir do cólon de camundongos ( $n = 3$ ), conforme descrito em estudos prévios (SAYED et al., 2020b, 2021; SAYED; CHAKRABORTY; DAS, 2023). Os tecidos foram digeridos

pela enzima colagenase, a 37°C durante 20-30 minutos. As células foram então filtradas e cultivadas em meio condicionado (CM) a 50%, o qual proporciona a proliferação das células-tronco adultas extraídas do tecido. Para o desenvolvimento dos organóides é necessário a adição de uma solução que mimetiza a matriz extracelular. Para isso foi utilizado Matrigel® (Corning) para cultivo de organóides. Meio CM fresco a 50% foi adicionado a cada 2-3 dias e os organóides utilizados nos experimentos estavam em passagens iniciais (p2-p8).

#### *Desenvolvimento de monocamadas polarizadas diferenciadas em suportes permeáveis de 96 poços*

Organóides cultivados saudáveis foram tripsinizados em células únicas e diferenciados em monocamadas polarizadas derivadas de enteróides (EDMs), conforme descrito anteriormente com pequenas modificações (SAYED et al., 2020b, 2021; SAYED; CHAKRABORTY; DAS, 2023). Os suportes permeáveis de 96 poços (HTS Transwell®, Corning Incorporated®, EUA) foram revestidos com Matrigel® (Corning Incorporated®, EUA) diluído (1:40). Cerca de  $5 \times 10^4$  células foram suspensas em meio condicionado a 5% e semeadas no transwell. A diferenciação das células em EDMs ocorreu em 2-3 dias e as células foram então utilizadas nos experimentos.

#### *Tratamento das EDMs diferenciados com LPS e AnxA-1 ou Ac2-26*

As EDMs diferenciados foram desafiados ou não (não tratados) com LPS (*E. coli*, O111:B4, Sigma-Aldrich) na concentração de 500 ng/mL nos compartimentos basolateral e apical por 24 horas. AnxA1 e Ac2-26, na concentração de 50 ng/mL, foram adicionados com o LPS durante todo o tempo experimental. As células foram monitoradas microscopicamente quanto à morfologia e viabilidade.

#### *Mensuração da resistência elétrica transepitelial (TEER) e avaliação do ensaio de permeabilidade transepitelial FITC-Dextran*

A permeabilidade nas células epiteliais intestinais diferenciadas foi medida por duas abordagens: o ensaio de permeabilidade de FITC-dextran e TEER. Para as medidas de TEER, foi utilizado o medidor de resistência epitelial Voltímetro Millicel-ERS (Millipore®, ©Merck, Alemanha) para medir o valor de TEER em diferentes momentos. Os valores de TEER foram expressos como Ohm x cm<sup>2</sup>. Para o ensaio de permeabilidade transepitelial FITC-Dextran, utilizamos isotiocianato de fluoresceína

conjugado ao dextram (peso molecular médio 40.000, ©Sigma-Aldrich). Ao final do experimento, 100 µL de FITC-dextram (1 mg/mL) foram adicionados ao compartimento apical do *transwell*, os meios foram recolhidos do compartimento basolateral após 1 hora e a fluorescência mensurada a 490 nm (excitação) e 520 nm (emissão) por leitor de placas Tecan (Tecan Trading AG, Suíça).

#### *Quantificação de citocinas liberadas das EDMs*

Os sobrenadantes foram coletados da parte basolateral das EDMs desafiados ou não com LPS +/-, AnxA1 ou Ac2-26. A concentração de ligante 1 de quimiocina (CXCL-1) de camundongo foi medido usando CXCL1/KC DuoSet™ ELISA de camundongo (©R&D Systems, EUA) de acordo com as instruções do fabricante. As concentrações de citocinas CXCL-1 foram comparadas nos EDMs +/- LPS +/- ANXA1 ou Ac2-26.

#### *Quantificação dos níveis de RNA por RT-qPCR*

Após desafio com LPS +/-, as EDMs tratadas com Anxa1 ou Ac2-26 foram lisados e o RNA isolado utilizando o kit Quick-RNA MicroPrep (©Zymo Research Corporated, EUA) de acordo com as instruções do fabricante. O RNA foi então utilizado para sintetizar DNA complementar (cDNA) usando qScript cDNA SuperMix (©Quantabio, EUA) de acordo com as instruções do fabricante. O RT-qPCR foi realizado usando 2x SYBR Green qPCR Master Mix em um equipamento Bio-Rad CFX Opus 96 Real-Time PCR System (©Bio-Rad, EUA) usando os primers listados na Tabela 6.

**Tabela 6.** Sequencia de primers utilizados nesse estudo

Primers	Forward primer (3' - 5')	Reverse primer (3' - 5')
18S rRNA	GTAACCCGTTGAACCCCAT	CCATCCAATCGGTAGTAGCG

Fonte: o autor

O *cycle threshol* (ct) foi determinado e normalizado para o gene endógeno (18S rRNA e GAPDH). O método  $\Delta\Delta C_t$  foi utilizado para o cálculo. A alteração relativa de duplicação do nível de transcrição foi calculada (*Fold change*).

#### *Avaliação das proteínas de integridade de TJ por microscopia confocal*

As EDM foram plaqueadas em suportes *transwell* de 96 poços e o fundo dos suportes removidos e fixados em metanol a 100% (-20°C durante 20 minutos) ou paraformaldeído a 4% (PFA, ©Sigma-Aldrich) à temperatura ambiente durante 15-20 minutos. As EDMs fixadas em PFA foram incubados à temperatura ambiente durante 10 minutos com glicina 100 mM. Após a fixação, todas as EDMs foram lavadas com PBS, permeabilizados com saponina a 0,1% à temperatura ambiente durante 10 minutos e bloqueados com tampão de bloqueio (saponina a 0,1% e BSA a 2%) durante 1 hora. As células foram marcadas utilizando anticorpo anti-ZO-1 (1:500) (©Proteintech Group, EUA) ou anti-claudina-2 (1:100, ©Abcam) diluídos em BSA a 1%, saponina 0,05 % e mantidas por 16 horas, a 4°C. Após as etapas de lavagem, as células foram incubadas com anticorpo secundário IgG Alexa Fluor 594 (1: 500,

Thermo Fisher) e DAPI (1:1000, Sigma-Aldrich) para coloração nuclear durante 1 hora à temperatura ambiente. As membranas EDM foram colocadas em uma lâmina de vidro, montadas com solução para montagem ProLong™ Glass (©Thermo Fisher Scientific, EUA) e cobertas com uma lamínula. As imagens foram tiradas com objetiva de 40x usando um microscópio confocal de varredura a laser Leica SP8 II (©Leica Microsystems, EUA). A intensidade da coloração foi avaliada pelo software ImageJ.

### **Análise estatística**

As análises estatísticas foram realizadas com o software GraphPad Prism Software 10.1. As análises clínicas *in vivo* foram avaliadas por ANOVA Two-Way seguido de pós-teste de Bonferroni. Os resultados obtidos para RT-PCR foram comparados usando um Teste *t* de Student bicaudal. Para as demais análises, foram utilizados One-way ANOVA seguido dos pós-teste de Tukey. Os valores de  $p < 0,05$  foram considerados significantivos. Os resultados foram expressos como média  $\pm$  EPM.

# *Resultados*

## **MLNC-AnxA1 como plataforma de entrega da AnxA1**

### ***Formulação da MLNC-AnxA1***

Inicialmente, para padronização foram preparados 3 lotes individuais de LNC, MLNC e MLNC-AnxA1, os quais foram avaliados para os parâmetros de polidispersão (PDI), tamanho (nm), potencial zeta ( $\zeta$  – mV) e pH. As soluções de nanocápsulas foram avaliadas macroscopicamente e ambas as soluções apresentaram aspecto homogêneo, branco opalescente. Quando comparados, os tamanhos das nanocapsulas, MLNC (152,4 nm  $\pm$ 3,89) e MLNC-AnxA1 (162,8 nm  $\pm$ 11,61), apresentaram diâmetro médio superior a LNC (129,5 nm  $\pm$ 3,57), sendo estatisticamente significativo ( $p < 0,05$ ). A dispersão das partículas, representado pelo PDI, foi significativamente maior nos grupos MLNC e MLNC-AnxA1 quando comparadas ao grupo LNC (0,114  $\pm$ 0,01); no entanto, a dispersão de partículas no grupo MLNC-AnxA1 (0,216  $\pm$ 0,02) foi reduzida quando comparado ao grupo MLNC (0,269  $\pm$ 0,01). O potencial zeta da LNC (-12,5 mV  $\pm$ 1,37) apresentou valor negativo, e positivo para MLNC (15,5 mV  $\pm$ 0,70) e MLNC-AnxA1 (16,2 mV  $\pm$ 1,71), não sendo observada diferença entre as nanocapsulas contendo quitosana. A adição de quitosana à estrutura da LNC causou redução significativa do pH quando comparados aos demais grupos ( $p < 0,01$ ). A análise de concentração de partículas por mL foi realizada no equipamento NanoSight e demonstrou que a concentração de partículas por mL foi reduzida significativamente quando comparados os grupos LNC ( $3,6 \times 10^{13}$  part/mL  $\pm 6,5 \times 10^{12}$ ) e MLNC-AnxA1 ( $1,5 \times 10^{13}$  part/mL  $\pm 4,8 \times 10^{12}$ ) (Tabela 6).

**Tabela 7.** Análise físico-química das nanocápsulas

Parâmetros	Nanocápsulas		
	LNC	MLNC	MLNC-AnxA1
Dh	129 ± 3.57	152 ± 3.89 *	163 ± 11.61 **
PDI	0.11 ± 0.01	0.27 ± 0.01 ***	0.22 ± 0.01 *** §
mV	-12.5 ± 1.37	15.5 ± 0.70 ***	16.2 ± 1.71 ***
pH	4.52 ± 0.02	4.24 ± 0.09 **	4.23 ± 0.03 **
PND ( $\times 10^{13}/\text{mL}^{-1}$ )	3.63 ± 0.66	2.75 ± 0.65	1.55 ± 0.48 *

Valores expressos em erro padrão da média  $\pm$  SEM (n = 3). \*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$  vs LNC. §  $p < 0.05$  vs MLNC.

Ademais, a análise de rastreamento de NPs realizada no equipamento NanoSight demonstrou que as nanocapsulas funcionalizadas com AnxA1 sobrepõem às revestidas com quitosana (Figura 7), demonstrando que ocorre conjugação com a proteína de forma eficiente. Em relação a eficiência de encapsulação, ou seja, quanto de AnxA1 foi conjugada a MLNC, a suspensão apresentou 92,22% ( $\pm 1,47$ ) para a AnxA1 após realizada ultra filtração-centrifugação da MLNC-AnxA1.

**Figura 7.** Sobreposição das NPs funcionalizadas com AnxA1 sobre as nanocápsulas revestidas com quitosana

Gráfico obtido do equipamento NTA e processada com o software NTA 2.0 Analytical Software (NanoSight ®).

Utilizando a solução de MLNC-AnxA1, foram obtidas imagens de microscopia eletrônica de transmissão (MET) em diferentes aumentos. As imagens demonstraram que MLNC-AnxA1 manteve o formato esférico quando comparada a imagens de

micrografia realizadas em trabalhos anteriores (BENDER et al., 2014; CÉ et al., 2016) com a LNC e MLNC (20k, 50k, 100k e 300k) (Figura 8).

**Figura 8.** Análise de microscopia eletrônica de transmissão

As nanocápsulas MLNC-AnxA1 foram analisadas utilizando diferentes ampliações. (A) 50x barra = 500 nm; (B) 100x barra = 200 nm; e (C) 300x barra = 100 nm.

### ***Administração oral da MLNC-AnxA1 não apresentou eficácia terapêutica para a colite ulcerativa experimental***

Após a caracterização físico-química da MLNC-AnxA1, a eficácia terapêutica das nanocápsulas foi investigada no modelo experimental de colite. Os camundongos receberam DSS 2% durante 6 dias para indução da colite e a partir do 6º dia, os animais receberam tratamento por via oral com AnxA1 (100 µg/mL) ou MLNC-AnxA1 (100 µg/mL –  $3,1 \times 10^{12}$  partículas). Como esperado, a ingestão de DSS foi capaz de induzir colite como observado pelos parâmetros clínicos de perda de peso, escore de consistência das fezes, de presença de sangue nas fezes, comprimento do intestino e índice de atividade da doença, os quais foram similares aos dados obtidos anteriormente (DE PAULA-SILVA et al., 2016b; SENA et al., 2015b). De acordo com a Figura 9 (A-E), os tratamentos com AnxA1 ou MLNC-AnxA1 por via oral não foram capazes de alterar os danos causados na colite quando comparados com o grupo controle.

**Figura 9.** Tratamento com MLNC-AnxA1 por via oral após colite experimental induzida pelo DSS.

(A) Porcentagem de perda de peso; (B) Escore de sangue; (C) Escore de fezes; (D) IAD; (E) Comprimento do intestino. Os dados são expressos como  $\pm$  erro padrão da média de 5 animais por grupo. **##**  $p < 0,01$  vs *naive*. v.o: via oral. Naive: nenhum tratamento.

Para analisar os efeitos dos tratamentos sobre a estrutura do intestino, foram realizadas análises histopatológicas. Os animais tratados tanto com MLNC-AnxA1, quanto com AnxA1 apresentaram dano tecidual semelhante ao grupo que recebeu apenas o DSS. Pela análise do corte histológico, foi possível observar displasia (seta preta fina), edema (seta vermelha), degeneração das criptas (seta preta cheia), ulcerações na mucosa (seta amarela) e intenso infiltrado inflamatório (seta verde) nos 3 grupos de animais (DSS, DSS+MLNC-AnxA1, ou AnxA1), quando comparados com o grupo *naive* (Figura 10).

**Figura 10.** Micrografia histológica obtida da região distal do intestino.

Secções histológicas com 4  $\mu\text{m}$  de espessura, coradas com hematoxilina e eosina e observadas em um aumento de 10x demonstram a ausência de efeito terapêutico de MLNC-AnxA1 e AnxA1 sobre o intestino inflamado. Displasia (seta preta fina), edema (seta vermelha), degeneração das criptas (seta preta cheia), ulcerações na mucosa (seta amarela) e intenso infiltrado inflamatório (seta verde).

***Administração intraperitoneal, mas não intravenosa, de MLNC-AnxA1 foi eficaz no tratamento da colite experimental***

Dada a falta de eficácia terapêutica da administração oral do tratamento com MLNC-AnxA1 na colite experimental, optou-se por explorar outras vias de administração, incluindo intravenosa (i.v.) e intraperitoneal (i.p.). Foram estabelecidos cinco grupos experimentais, abrangendo diferentes condições: o grupo naive, sem DSS e tratamentos; o grupo controle, que recebeu apenas DSS; DSS+MLNC-AnxA1 (i.v.), DSS+MLNC-AnxA1 (i.p.) e DSS+AnxA1 (i.v.). Os protocolos de tratamento seguiram o mesmo cronograma previamente utilizado para a administração oral. Dentre os parâmetros clínicos analisados, observou-se redução significativa nos escores de fezes, de sangue e no IAD nos animais tratados com MLNC-AnxA1 (i.p.), quando comparados ao grupo controle que recebeu apenas DSS. O comprimento do intestino nos animais tratados com MLNC-AnxA1 (i.p.) foi equivalente ao grupo naive e significativamente maior do que nos animais que receberam apenas DSS, sugerindo que o tratamento com MLNC-AnxA1 i.p. favoreceu a recuperação tecidual após o dano causado pelo DSS. Surpreendentemente, a administração tanto de MLNC-AnxA1 quanto de AnxA1 via i.v. não apresentou diferenças significativas em nenhum dos parâmetros clínicos avaliados em comparação com o grupo controle (Figura 11A-F).

**Figura 11.** Painel clínico do tratamento i.p. e i.v. de MLNC-AnxA1.

(A) Porcentagem de perda de peso; (B) Escore de fezes; (C) Escore de sangue; (D) IAD; (E) comprimento do intestino; (F) Imagens capturadas dos intestinos coletados no dia da eutanásia, comparando o comprimento entre cada grupo. Os dados são expressos como  $\pm$  erro padrão da média de 6 animais por grupo \* $p < 0,05$ , \*\* $p < 0,01$ , \*\*\* $p < 0,001$  vs controle. && $p < 0,001$  vs MLNC-AnxA1(i.v.). # $p < 0,05$ , ## $p < 0,01$  vs naive.

Com base nos resultados previamente obtidos, um novo experimento de colite foi realizado com o intuito confirmar a efetividade do tratamento via i.p. e analisar o perfil celular da lâmina própria. O tratamento i.p. com MLNC-AnxA1 foi eficaz na redução dos sintomas da colite. Observou-se redução significativa na perda de peso, na diarreia e no índice de atividade da doença (Figura 12A-D), bem como a restauração da integridade estrutural do cólon, evidenciada pela recuperação do comprimento intestinal no 10º dia após a ingestão de DSS (Figura 12E-F).

**Figura 12.** Papel da terapia com MLNC-AnxA1 na atividade da colite induzida por DSS e na estrutura intestinal.

Os camundongos foram tratados com DSS 2% para desenvolver colite e foram tratados com rAnxA1 (12,5 µg/mL), MLNC (9,6x10<sup>11</sup> partículas) ou MLNC-AnxA1 (9,6x10<sup>11</sup> partículas/12,5 µg) entre os dias 6 e 9. (A) Percentual de perda de peso corporal; (B) Escore de diarreia; (C) Escore de sangue oculto; (D) DAI; (E) Comprimento intestinal; (F) Avaliação anatômica do cólon. n = 6 camundongos/grupo. \*p < 0,05, \*\*p < 0,01, \*\*\*p < 0,001 vs DSS.

LNC, nanocápsula com núcleo lipídico; MLNC, nanocápsula com núcleo lipídico multiparede; MLNC-AnxA1, nanocápsula de núcleo lipídico multiparede de complexo metálico; DAI, índice de atividade da doença.

A partir dos leucócitos extraídos da lâmina própria foi possível observar que a ingestão de DSS aumentou significativamente a porcentagem de neutrófilos (Ly6G<sup>+</sup>; Figura 13A) e macrófagos (F4/80<sup>+</sup>; Figura 13B), refletindo aumento na quantidade de macrófagos do tipo M1 (F4/80/CD80<sup>+</sup>; Figura 13C). Nenhum dos tratamentos reduziu a quantidade de neutrófilos e macrófagos (Figura 13A e 13B); no entanto, o tratamento com MLNC-AnxA1 reduziu a quantidade de macrófagos do tipo M1 (F4/80/CD80<sup>+</sup>; Figura 13C), e tanto os tratamentos com AnxA1 quanto MLNC-AnxA1 aumentaram a quantidade de macrófagos do tipo M2 (F4/80/CD206<sup>+</sup>; Figura 13D).

**Figura 13.** MLNC-AnxA1 regula positivamente a polarização de macrófagos M2 na lâmina própria.

As células foram dissociadas por atividade enzimática da matriz extracelular e  $2 \times 10^5$  células foram utilizadas para marcação de anticorpos. (A) Ly6G+, (B) F4/80+, (C) F4/80+CD80+, (D) F4/80+CD206+, n = 6 camundongos/grupo. \* $p < 0,05$ , \*\* $p < 0,01$  vs DSS. # $p < 0,05$ , ## $p < 0,01$  vs Naive.

***O tratamento intraperitoneal com MLNC-AnxA1 recuperou a histoarquiteta e proteínas relacionadas à proliferação e estrutura epitelial***

A ingestão de DSS causou danos severos ao tecido colônico de camundongos e atingiram a pontuação histológica mais alta em todos os parâmetros (Figura 14A): edema tecidual (linha pontilhada), displasia/alteração da histoarquiteta (seta preta), edema de cripta (seta amarela), infiltrados inflamatórios (seta branca) e úlceras (seta preta). Os camundongos tratados com MLNC apresentaram pontuações histológicas elevadas, semelhantes às do grupo DSS (Figuras 14G e H), enquanto o tratamento com AnxA1 promoveu melhorias nas pontuações histológicas, reduzindo alguns parâmetros como edema e displasia/alteração da histoarquiteta (Figura 14E e F). No entanto, apenas o tratamento com MLNC-AnxA1 levou à recuperação da histoarquiteta colônica durante a colite, diminuindo o edema de cripta, infiltrados inflamatórios e úlceras, em comparação ao grupo DSS (Figuras 14I e J). O grupo naive apresentou histoarquiteta normal, como esperado (Figura 14B).

**Figura 14.** Análise histopatológica da região proximal do cólon.

(A) Pontuação histopatológica representada por unidades arbitrárias. As secções foram avaliadas cegamente e as alterações consideradas foram destacadas. Edema tecidual (linha pontilhada), displasia/histoarquitetura alterada (ponta de seta preta), edema de cripta (ponta de seta amarela), infiltrados inflamatórios (ponta de seta branca) e ulcerações (seta preta). (B) Naive apresentando histoarquitetura normal, com epitélio cilíndrico simples (quadrado preto); (C e D) grupo DSS; (E e F) grupo AnxA1; (G e H) grupo MLNC; (I e J) grupo MLNC-AnxA1.  $n = 6$  camundongos/grupo. Barra de escala: 50  $\mu\text{m}$ . Secções: 4  $\mu\text{m}$ . Aumento óptico de 20x. \* $p < 0,05$  vs DSS. § $p < 0,05$  vs AnxA1. & $p < 0,05$  vs MLNC. ## $p < 0,01$  vs Naive.

Ademais, a área marcada para as proteínas de junção epitelial Claudina-1 e ZO-1 foi reduzida nos camundongos DSS (Figura 15B e G) em comparação com o grupo naive (Figura 15A e F). Os tratamentos com AnxA1 e MLNC-AnxA1 restauraram a expressão de Claudina-1 (Figura 5H e J) e apenas MLNC-AnxA1 restaurou a expressão de ZO-1 (Figura 5E) em tecidos inflamados. O tratamento com MLNC apresentou o mesmo resultado que o DSS para a expressão de Claudina-1 (Figura 15I).

**Figura 15.** Efeitos do tratamento com MLNC-AnxA1 nas junções epiteliais.

(A e F) Grupo Naive; (B e G) grupo DSS; (C e H) grupo AnxA1; (D e I) grupo MLNC; (E e J) grupo MLNC-AnxA1. Os gráficos representam a percentagem (%) de área marcada para ZO-1 (K) e Claudina1 (L). (M) Seção de controle. n=6 camundongos/grupo. Fotos: aumento óptico 40x. Secções: 4 µm. Barra de escala: 100 µm. \*p<0,05, \*\*p<0,01 vs DSS. &p<0,05, &&p<0,01 vs. #p<0,05, ##p<0,01 vs Naive.

Adicionalmente, o número de núcleos proliferativos na camada mucosa foi avaliado contando células positivas para PCNA e Ki67 (Figura 16F e L). Para ambos os alvos, apenas o tratamento com MLNC-AnxA1 aumentou o número de núcleos positivos, principalmente na região basal, o que juntamente com os demais resultados é indicativo de epitélio regenerativo (Figura 16E e K). Nos outros grupos de tratamento houve um baixo número e desorganização estrutural de células positivas para PCNA (Figura 16G, H, I e J) e Ki67 (Figura 16A, B, C e D), que se distribuíram irregularmente por toda a extensão das células epiteliais. Além disso, foi encontrada coloração aumentada na zona apical do tecido nos grupos tratados com DSS, AnxA1 ou MLNC, o que pode ser indicativo de áreas de displasia.

**Figura 16.** Efeitos do tratamento com MLNC-AnxA1 na regeneração e renovação epitelial no cólon danificado pela colite induzida por DSS.

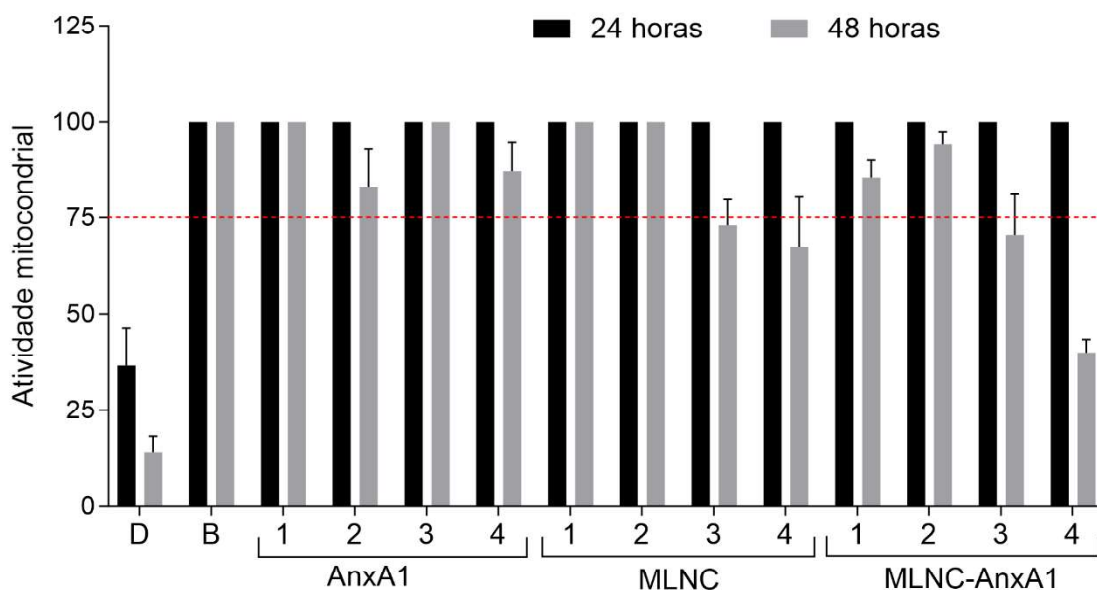

Ki67 e PCNA são representados em objetivas de 20x e 40x. (A e G) Grupo Naive; (B e H) grupo DSS; (C e I) grupo AnxA1; (D e J) grupo MLNC; (E e K) grupo MLNC-AnxA1. Barras: 50 µm e 20 µm. \* p<0,05 vs DSS. & p <0,05 vs MLNC.

### **MLNC-AnxA1 apresentou baixa citotoxicidade para macrófagos *in vitro***

Com base nos resultados *in vivo*, foram iniciados experimentos *in vitro* para elucidar o papel da MLNC e MLNC-AnxA1 sobre macrófagos murinos. Foram utilizadas células Raw 264.7 e, inicialmente, foram realizados ensaios para verificar a viabilidade celular frente aos tratamentos. O ensaio de MTT, o qual avalia a função mitocondrial, foi utilizado como teste de triagem da viabilidade. Os resultados obtidos demonstraram que as concentrações de MLNC  $68 \times 10^9$  e  $136 \times 10^9$  e de MLNC-AnxA1  $77,5 \times 10^9$  e  $150 \times 10^9$  apresentam atividade mitocondrial inferior a 75% após 48 horas, sugerindo efeito citotóxico. As reduções estão mostradas nas barras 3 e 4 da Figura 12, para os tratamentos com MLNC e MLNC+AnxA1. Os demais tratamentos com MLNC, MLNC-AnxA1 e AnxA1 apresentaram atividade mitocondrial superior a 75% em todos os tempos de tratamento (Figura 17).

**Figura 17.** Viabilidade celular relacionando a atividade mitocondrial pela técnica de redução do MTT

Os tratamentos da célula Raw 264.7 foram feitos com diferentes concentrações de AnxA1 (1) 50, (2) 500, (3) 2500 e (4) 5000 ng/mL; MLNC (1)  $1,3 \times 10^9$ , (2)  $13 \times 10^9$ , (3)  $68 \times 10^9$  e (4)  $136 \times 10^9$  partículas/mL e MLNC-Anxa1 (1)  $1,55 \times 10^9$ , (2)  $15 \times 10^9$ , (3)  $77,5 \times 10^9$  e (4)  $150 \times 10^9$  partículas/mL) mantidas por três tempos: 24 e 48 horas. Como controle positivo para dano mitocondrial foi utilizado o DMSO (D) 5%. Como controle negativo foi utilizado PBS para resultado basal (B). Os dados são expressos como  $\pm$  erro padrão da média de 4 experimentos individuais.

Para identificar o impacto na viabilidade celular, células Raw 264.7 foram tratadas com MLNC e MLNC-AnxA1 apenas nas concentrações que causaram menor

atividade mitocondrial no ensaio de MTT e com a maior concentração de AnxA1. Como marcadores de citotoxicidade foram utilizadas a dupla marcação de Anexina V e 7-AAD, e como marcador de célula viável foi utilizada a calceína 0,01 M. Observou-se viabilidade superior a 75% apenas no grupo que recebeu AnxA1 em todos os tempos analisados, enquanto os demais tratamentos com MLNC e MLNC-AnxA1 apresentaram redução da viabilidade celular. Os tratamentos com MLNC ( $136 \times 10^9$  partículas/mL (barra 3)) e MLNC-AnxA1 ( $77,5 \times 10^9$  (barra 3) e  $50 \times 10^9$  (barra 4) partículas/mL contendo, respectivamente, 2500 e 5000 ng/mL de AnxA1 na LMNC aumentaram significativamente a frequência de células necróticas e em apoptose tardia após incubação de 72 h (Figura 18).

**Figura 18.** MLNC e MLNC-AnxA1 promoveram aumento de células necróticas e em apoptose tardia após 72 horas de incubação.

Células Raw 264.7 foram tratadas AnxA1, MLNC ou MLNC-AnxA1 e analisadas em diferentes tempos. (A) Porcentagem de células viáveis marcadas com calceína 0,01M; (B) Porcentagem de células em apoptose marcadas com Anexina V; (C) Porcentagem de células em necrose marcadas com 7-AAD;

(D) Porcentagem de células em apoptose tardia identificadas pela dupla marcação com anexina V e 7-AAD. \* $p < 0,05$  vs não tratado e \*\* $p < 0,01$  vs não tratado. N experimental = 4.

***MLNC-AnxA1 foi internalizada por macrófagos e promoveu resposta anti-inflamatória***

Os resultados obtidos no ensaio de citotoxicidade indicaram duas concentrações seguras para análise pelos ensaios de captação celular. As concentrações empregadas para avaliação da capacidade de captação celular foram de MLNC ( $13 \times 10^9$  partículas/mL) e MLNC-AnxA1 ( $13 \times 10^9$  partículas/mL). Utilizando a técnica de microscopia confocal de campo escuro de alta resolução, que demonstra maior refringência no interior celular é possível observar a presença de NPs no citoplasma celular, que ocorre pelo aumento da absorção de luz por essas NCs. As imagens obtidas demonstram internalização em células Raw 264.7 de MLNC após 2 horas de incubação, enquanto não foi observado internalização de MLNC-AnxA1 neste mesmo tempo de incubação. Após incubação com 24 horas foi possível perceber que ambas, MLNC e MLNC-AnxA1, se encontravam no interior celular, demonstrando que a presença de AnxA1 na estrutura da nanocápsula aumentou o tempo para captação celular (Figura 19).

**Figura 19.** Análise de uptake celular em células Raw 264.7 por CytoViva®

Células Raw 264.7 foram plaqueadas na concentração de  $8 \times 10^4$  células/poço e tratadas nos tempos de 2 e 24 horas com MLNC ( $13 \times 10^9$  partículas/mL) e MLNC-AnxA1 ( $13 \times 10^9$  partículas/mL). As células foram fotografadas usando o sistema de imagem CytoViva Ultra Resolution (CytoViva, Inc., AL, EUA) montado em um microscópio Olympus BX51 (ampliação de 1500  $\times$ ; Olympus Corporation, Tóquio, Japão) equipado com uma abertura numérica (NA) de fluorita 100  $\times$  óleo de íris de 0,6-1,30 objetiva e fonte de luz 75 W Xe e as imagens comparadas com o grupo não tratado ([NT]).

Com base nos resultados *in vivo* que nos conduziram para um efeito mais pronunciado do tratamento da MLNC-AnxA1 sobre macrófagos, foram realizados experimentos *in vitro* para elucidar o papel da MLNC e MLNC-AnxA1 sobre a polarização destas células. Macrófagos primários obtidos de medula óssea de camundongos C57Bl/6 foram diferenciados primeiramente em macrófagos pró-

inflamatório M1 pela adição de LPS (100 ng/mL). Após 48h de tratamento com AnxA1, MLNC ou MLNC-AnxA1, apenas MLNC-AnxA1 aumentou a porcentagem de células F4/80<sup>+</sup>CD206<sup>+</sup>, com fenótipo M2 (Figura 20A). Foi observada diminuição da porcentagem de células F4/80<sup>+</sup>CD80<sup>+</sup> apenas no tratamento com AnxA1 (500ng/mL) (Figura 20B). Ainda, o tratamento com MLNC-AnxA1 sobre macrófagos M1 foi capaz de aumentar significativamente a concentração de TGFβ (Figura 20C). Ademais, não houve diferença na concentração de IL-10 no sobrenadante celular (Figura 20D).

**Figura 20.** 3 MLNC-AnxA1 estimula a polarização de macrófagos com fenótipo M2

(A) Macrófagos F4/80+CD80+, (B) Macrófagos F4/80+CD206+, (C) TGFβ no sobrenadante de cultura, (D) IL-10 no sobrenadante de cultura. \*p<0,05, \*\*p<0,01 e \*\*\*p<0,001 vs LPS (100 ng/mL). #p<0,05 e ##p<0,01 vs Dexametasona (500 ng/mL).

Concluindo, os dados apresentados acima mostraram a MLNC foi capaz de carrear a rAnxA1, e que a MLNC-AnxA1 foi efetiva para tratar a colite experimental pela via i.p. sendo que os efeitos observados foram mais significativos que os desencadeados pela rAnxA1 livre. No entanto, o projeto tinha como propósito carrear a AnxA1 ou seu peptídeo mimético Ac2-26 por via oral, como uma proposta de um tratamento não invasivo. Abaixo seguem os resultados das estratégias empregadas para atingir este objetivo e as eficácias terapêuticas obtidas.

## **SBA-15 funcionou como plataforma de entrega do peptídeo Ac-2-26 por via oral**

### ***A solução Ac2-26 é composta por partículas semelhantes a bastonetes***

Ac2-26 foi disperso com sucesso em água deionizada a uma concentração de 6 mg/mL, permitindo experimentos futuros que poderiam exigir concentrações mais elevadas. É interessante observar que a amostra foi mais viscosa que a água pura e levemente turva, o que indicou a provável existência de grandes agregados, sendo essas características atenuadas após a diluição. Para analisar tais agregados, foram realizados ensaios de DLS. A Figura 21A mostra a função de autocorrelação obtida (círculos preenchidos em preto),  $C(\tau)$  foi ajustado com um método adequado para o modelo (no caso, *Non-Negatively constrained Least Squares*, NNLS). A partir do ajuste satisfatório, avaliou-se a distribuição de tamanho ponderada por intensidade, volume e número (inseridos na Figura 1A). A intensidade espalhada é diretamente proporcional ao quadrado do volume da partícula (ou, de maneira equivalente, ao seu raio/diâmetro elevado a sexta potência). Conforme observado, existem três populações de partículas com tamanhos  $(23 \pm 1)$  nm,  $(109 \pm 28)$  nm e  $(58 \pm 18)$   $\mu$ m, sendo a primeira a mais numerosa.

Considerando os resultados, nenhum desses conjuntos corresponde ao peptídeo sozinho, com apenas 3.089,46 Da de peso molecular, conforme informado pelo fabricante, mas sim à sua estrutura supramolecular automontada e até mesmo agregados. Para confirmar esta característica, foram realizados experimentos SAXS na mesma amostra usada para DLS.

**Figura 21.** Parâmetros físicos de SBA-15, Ac2-26 e SBA-16-Ac2-26

(A) Função de autocorrelação (círculos pretos preenchidos) ajustada pelo método NNLS (linha contínua). Inserção: Distribuições de diâmetro hidrodinâmico do peptídeo ponderadas por número, volume e intensidade. (B) Dados SAXS do peptídeo em solução (círculos preenchidos) ajustados pelo método IFT (linha contínua azul) e o modelo do cilindro (linha contínua vermelha). Inserção: A função  $p(r)$  obtida, do IFT, e a função de distribuição de tamanho do raio do cilindro,  $N(D)$ , do ajuste do modelo. (C) Dados de SAXS (círculos pretos preenchidos) de SBA-15 pura e de SBA-15 incorporada com Ac2-26 (amostra SBA15-Ac2-26) ajustado pelo modelo SBA-15 (linha contínua vermelha). As curvas foram deslocadas verticalmente para uma visualização mais clara. (D) Dados de NAI de SBA-15 pura e SBA-15 incorporado com Ac2-26 (amostra SBA-Ac-26). Inserção: Distribuição do tamanho dos poros (PSD, adsorção e dessorção).

Os dados obtidos a partir da análise de SAXS estão mostrados na Figura 21B (círculos preenchidos em preto) e foram ajustados pela *Indirect Fourier Transform* (IFT), que permite obtermos informações da partícula no espaço real, representado pela função de distribuição de distância de pares, implementada no software WIFT (GLATTER, 1977). A partir do ajuste (linha contínua azul), foi obtida a chamada distribuição de distâncias de pares,  $p(r)$ , (inserção da Figura 21B, linha contínua azul), que fornece o maior comprimento da partícula de  $\sim 23$  nm (onde  $p(r) \approx 0$ ), compatível com os resultados do DLS relativos à população com os menores objetos. Além disso, a distribuição de distâncias de pares,  $p(r)$ , sugeriu a presença de partículas alongadas,

com formato de bastonete. Neste contexto, foi realizado um teste no qual os dados de SAXS foram ajustados a um modelo de cilindro simples. Também foi utilizada uma distribuição de tamanho log normal para os valores dos raios, como em trabalhos anteriores (Pinto Oliveira, 2011). O ajuste satisfatório obtido (Figura 21B, linha contínua vermelha), corroborou a hipótese do formato cilíndrico. Neste caso, os objetos possuem raio médio de ~3 nm, de acordo com a distribuição de tamanho obtida (inserção da Figura 21B, linha vermelha contínua) e comprimento de ~80 nm. O primeiro valor ficou fora do comprimento da escala definido pelo valor mínimo da faixa  $q$ , portanto não pode ser determinado com precisão. Assim, o valor determinado pela função  $p(r)$ , ~23 nm, foi assumido como o comprimento do cilindro. Em suma, os resultados de SAXS e DLS sugerem arranjo do peptídeo em partículas em forma de bastonete com comprimento de 23 nm e diâmetro de 6 nm, aproximadamente.

### ***Micropartícula mesoporosa SBA-15 foi eficiente para ancorar o Ac2-26***

A incorporação do peptídeo a SBA-15 foi de cerca de  $88,8\% \pm 1,2$  ( $n=4$ ), medida pelo método de ligação ao corante de Bradford. As medições de SAXS foram realizadas em amostras seca de SBA-15 e SBA-15-Ac2-26 (Figura 21C). Para descrever quantitativamente sua nanoestrutura e eventuais diferenças, procedemos à análise dos dados utilizando o modelo totalmente detalhado por Losito et al 2021a. Os principais parâmetros de ajuste, bem como seus valores, estão resumidos na Tabela 8, e seu significado é explicado a seguir:  $R$  e  $T$  correspondem ao raio do núcleo e à espessura da parede, respectivamente, do cilindro núcleo-parede que modela os mesoporos, sendo  $\sigma_{rel}$  o desvio padrão compartilhado da distribuição de tamanho log-normal de  $R$  e  $T$ . O parâmetro  $\frac{\Delta\rho_{núcleo}}{\Delta\rho_{parede}}$  informa sobre a densidade eletrônica de contraste do núcleo em relação à parede. Para idealmente “vazio”,  $\frac{\Delta\rho_{core}}{\Delta\rho_{shell}} = 0$ . Diferente de,  $\frac{\Delta\rho_{core}}{\Delta\rho_{shell}} \neq 0$  é um indício da existência de algum material no interior dos mesoporos.  $a$  é o parâmetro de rede e  $\sigma_a$  quantifica a distorção da rede em relação a uma rede hexagonal 2D ideal (para uma rede ideal,  $\sigma_a = 0$ ). Por fim,  $AP$  é o fator de Porod (proporcional a  $q^{-4}$  lei decadente) e monitora a presença de grandes agregados, enquanto o fator  $R_{G_{polymer}}$  analisa o contraste de densidade eletrônica relativa e quantifica a presença de material dentro dos mesoporos. Como esperado, ambas as curvas possuem parâmetros estruturais com valores próximos, exceto o

parâmetro AP. Em comparação ao SBA-15 puro, seu valor aumentou 3 vezes com a adição do peptídeo, o que sugere a presença de material na macroporosidade do SBA-15. Além disso, o parâmetro  $\Delta\rho_{núcleo}/\Delta\rho_{parede}$  aumentou ligeiramente com a incorporação do peptídeo, indicando que uma fração do material está dentro dos mesoporos. Considerando que a porcentagem de ancoragem peptídica foi de 88%, conforme discutido anteriormente, possivelmente a maior parte do Ac2-26, em sua forma agregada/automontada, está na macroporosidade SBA-15.

Para obter mais informações sobre o preenchimento dos poros de SBA-15 pelo peptídeo, foram realizados experimentos NAI. Os resultados de sorção relacionados às amostras de SBA-15, puras e carregadas com Ac2-26 (peptídeo:sílica, 1:35% em peso), são mostrados na Figura 21D. A isoterma de ambas as amostras mostra *loops* de histerese com ramificações acentuadas de adsorção e dessorção, o que indica uma estreita distribuição de tamanho de poros. As distribuições de tamanho dos poros tanto para a adsorção quanto para a dessorção foi obtido com base nos métodos Brunauer–Emmett–Teller (BET) e Barrett–Joyner–Halenda (BJH) (inserção da Figura 21D) juntamente com outros parâmetros resumidos na Tabela 7. Embora a distribuição do tamanho dos poros de ambas as amostras seja muito semelhante, os dados apresentados na Tabela 7 mostram uma redução de cerca de 55% na área superficial (mesoporosidade interna x macroporosidade externa) após a incorporação do peptídeo na SBA-15. Considerando também a redução de ~62% no volume disponível dos mesoporos, o que pode indicar seu preenchimento ou bloqueio da entrada dos poros. Podemos concluir assim que o peptídeo está localizado dentro da porosidade da sílica (mesoporos e/ou macroporos).

**Tabela 8.** Propriedades estruturais e texturais das amostras de SBA-15

Técnica	Parâmetro físico avaliado em cada técnica	Amostras	
		SBA-15	SBA-Ac2-26
SAXS	$R$ [nm]	4.37(1)	4.37(9)
	$T$ [nm]	2.56(3)	2.53(2)
	$\sigma_{rel}$ [%]	7.2(2)	7.8(9)
	$\frac{\Delta\rho_{core}}{\Delta\rho_{shell}}$	0.000(1)	0.006(1)
	$a$ [nm]	11.33(1)	11.33(1)
	$\sigma_a$ [nm]	0.044(6)	0.041(4)
	$AP \times 10^{-8}$	7.2(7)	20.8(2)
	$R_{G_{polymer}}$ [Å]	6.7(6)	8.1(5)
NAI	BET área superficial [m <sup>2</sup> /g]	768 (1)	342 (1)
	Diminuição área superficial [%]	***	55
	BJH Volume do mesoporo [cm <sup>3</sup> /g]	1.74 (1)	0.65 (1)
	Preenchimento do poro [%]	***	62
	Diâmetro médio dos poros(ads) [nm]	9.4 (1)	9.5 (1)
	Diâmetro médio dos poros(des) [nm]	7.5 (1)	7.6 (1)
	Espessura da parede [nm]	1.9 (1)	1.8 (1)

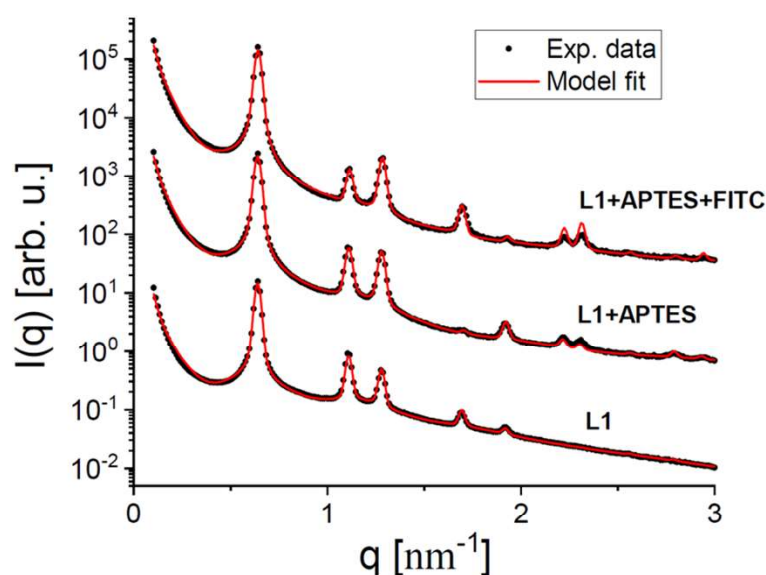

Amostra SBA-15 e SBA-15 incorporada com Ac2-26 (amostra SBA-Ac-26) obtida pelas técnicas SAXS e NAI. O erro está apresentado entre parênteses.

Em conjunto com os resultados do SAXS, a hipótese de que provavelmente a maior parte do peptídeo estava na macroporosidade SBA-15 foi reforçada. Além disso, ficou evidente a possibilidade de aumento da concentração do peptídeo, com o cuidado de preservar uma distribuição homogênea, uma vez que ainda existia “espaço livre” na porosidade do SBA-15.

### **SBA-15 não causou citotoxicidade e liberou Ac2-26**

A marcação com fluoróforo foi empregada para investigar a captação de SBA-15 e a liberação do Ac2-26 pelo SBA-15 nas células. A medição SAXS mostrou a incorporação do fluoróforo ao SBA-15 sem alterações robustas no perfil de espalhamento do SBA-15 (Figura 22).

**Figura 22.** Dados de análise de SAXS para SBA15-FITC

Dados de SAXS (círculos pretos preenchidos) de SBA-15 pura e de SBA-15 incorporada com FITC (amostra SBA-FITC) ajustado pelo modelo SBA-15 (linha contínua vermelha). L1: corresponde ao nome do lote de SBA-15 utilizado. APTES: 3-aminopropiltrimetoxissilano

A captação de SBA-15 por células epiteliais colônicas diferenciadas demonstrou baixa potencial de internalização de micropartículas (Figura 23A e D) bem como em organoides colônicos 3D (Figura 23B), que indicam que SBA-15 pode ser pouco absorvido no intestino. Além disso, análises adicionais de citometria de fluxo confirmaram esses dados (dados não apresentados). No entanto, o aumento da permeabilidade epitelial ou mesmo a ruptura da barreira epitelial que ocorre durante a inflamação intestinal pode favorecer o influxo de micropartículas para o tecido.

Os dados apresentados na Figura 23C mostraram que os macrófagos murinos J774 internalizaram a micropartícula por fagocitose, uma vez que a porcentagem de ingestão foi bloqueada pela citocalasina D com uma concentração de 20  $\mu\text{M}$ . A captação de micropartículas aumentou com o tempo (Figura 23E e F) e não causou citotoxicidade até 48 horas de incubação (Figura 23G).

Para avaliar a entrega de Ac2-26 por SBA-15, as células epiteliais Caco-2 foram incubadas com SBA-15 marcado com Ac2-26-Cy5.5. O ensaio de citometria de fluxo detectou fluorescência emitida por Ac2-26-Cy5.5 nas células epiteliais após 30 minutos de incubação, que aumentou progressivamente após 6 horas de incubação (Figura 23H). Além disso, dados semelhantes foram encontrados em macrófagos Raw 264.7, o que também evidencia a capacidade do SBA-15 de entregar o peptídeo em fagócitos (Figura 23H).

**Figura 23.** Internalização de SBA-15-FITC e SBA-15-Ac2-26-Cy5.5

(A) Fotos representativas de EDMs diferenciados tratados com FITC-SBA por 24 horas. (D) A porcentagem de absorção de micropartículas foi determinada. (B) Imagens representativas mostraram organoides murinos 3D desafiados com micropartículas e cultivados por 6 dias. (C) Imagens representativas mostraram macrófagos J774 desafiados ou não com micropartículas por 24 horas na presença ou ausência de inibidores de fagocitose (citocalasina D). (E) e (F) representam a quantificação da captação de FITC-SBA após 4 horas (4h) e 24 horas (24h) após o tratamento. ### **Eudragit-SBA-15 foi distribuído no trato gastrointestinal (TGI) e entregou o peptídeo Ac2-26 no intestino**

A análise de dissolução *in vitro* mostrou que o peptídeo Ac2-26 foi liberado do Eudragit-SBA-15 em uma solução de pH próximo ao encontrado no duodeno (Figura 25).

**Figura 24.** Ensaio de liberação do peptídeo em diferentes pH

Eud-SBA-15-Ac2-26 foi colocado em solução com diferentes pH e a liberação de Ac2-26 pela SBA-15 quantificada. O resultado está expresso em porcentagem de liberação de peptídeo em relação a concentração inicial de 2 mg. \*\*\*\*  $p < 0,0001$  vs pH 1,2.

Para confirmar se o peptídeo foi entregue no intestino, Eudragit-SBA-15-Ac2-26-Cy.5.5 foi administrado por via oral, e a intensidade da fluorescência foi alcançada no TGI após 3 horas de administração, permanecendo por até 8 horas de análise (Figura 25A).

Para avaliar o trânsito de Eudragit-FITC-SBA-15 nas condições do TGI e a capacidade de atingir o intestino grosso, rastreamos o tratamento por 6 e 18 horas após a administração oral em camundongos. A medição dos sinais detectou o Eudragit-FITC-SBA-15 nos intestinos delgado e grosso às 6 horas e 18 horas após a administração, respectivamente (Figura 26B). Os dados obtidos mostraram que o

Eudragit-SBA-15 permanece no TGI durante pelo menos 18 horas, o que pode levar à liberação sustentada do peptídeo no intestino, o que pode ser um fator relevante e desejado para a eficácia terapêutica do Eudragit-SBA-15-Ac2-26 por via oral em DII.

**Figura 25.** Biodistribuição ao longo do TGI de Eudragit-SBA15-Ac2-26Cy5.5 Eudragit-FITC-SBA-15

Os camundongos foram tratados por via oral e a intensidade da distribuição é representada por fótons/s. (A) distribuição de Eudragit-SBA15-Ac2-26Cy5.5 foi analisada após 3 horas e 8 horas *in vivo* (parte superior) e o TGI analisado separadamente *ex vivo* (parte inferior) nos mesmos tempos. A cor amarela representa a maior intensidade no tecido. (B) Biodistribuição de Eudragit-FITC-SBA-15 *ex vivo* ao longo do TGI após 6 horas e 18 horas. A cor vermelha representa a maior intensidade no tecido.

### **Administração oral do Eudragit-SBA15-Ac2-26 reduziu sintomas clínicos e inflamação no intestino**

A administração de DSS por via oral desencadeou o pico da doença no dia 6, e a retirada do DSS resulta na recuperação inicial do tecido a partir do dia 10. Assim, o tratamento oral com Eudragit-SBA-15-Ac2-26 começou no pico da doença (dia 6) e foi mantida até o início da fase de recuperação (dia 10). Os dados obtidos mostraram que a administração oral de Eudragit-SBA-15-Ac2-26 preveniu a perda de peso e induziu a recuperação do comprimento do cólon, levando a um menor DAI, apesar de não alterar a consistência e sangue nas fezes (Figura 26A-F).

**Figura 26.** Perfil clínico de camundongos com colite induzida por DSS tratados com Eudragit-SBA-15 ou Eudragit-SBA15-Ac2-26

(A) Porcentagem de perda de peso corporal; (B) Escore de consistência das fezes; (C) Escore de sangue nas fezes; (D) IAD; (E) Medida de comprimento do cólon; (F) Avaliação anatômica do cólon. n = 10 animais/grupo. \* p<0,05, \*\* p < 0,01, \*\*\* p< 0,001 vs DSS. & p<0.05, && p<0,01, &&& p< 0.001 vs Eudragit-SBA-15.

Ainda, o tratamento inibiu o influxo de neutrófilos e macrófagos para o intestino inflamado (Figura 27A e B), reduziu a secreção das citocinas inflamatórias TNF $\alpha$  e CXCL-1 e aumentou a secreção da citocina anti-inflamatória IL-10 (Figura 27C-E). Os efeitos benéficos do tratamento foram devidos à carga de Ac2-26, uma vez que o tratamento com Eudragit-SBA-15 não preveniu sintomas clínicos e parâmetros de inflamação (Figura 26A-F).

**Figura 27.** Perfil celular e secretório do cólon

(A) Porcentagem de macrófagos isolados da lamina própria (CD45<sup>+</sup>/F4/80<sup>+</sup>); (B) Porcentagem de neutrófilos isolados da lâmina própria (CD45<sup>+</sup>/Ly6G<sup>+</sup>); (C) TNF- $\alpha$ ; (D) CXCL-1; (E) IL-10. n = 10 animais/grupo. \* p<0.05, \*\* p<0.01, \*\*\* p<0.001, \*\*\*\* p<0.0001 vs DSS. & p<0,05, && p<0,01, &&& p<0,001 vs Eudragit-SBA-15.

### **Administração oral do Eudragit-SBA15-Ac2-26 recuperou a histoarquitetura intestinal**

A análise histológica do tecido mostrou que a administração de DSS induziu úlceras, abscessos nas criptas, degeneração hidrópica vacuolar, edema submucoso e infiltrado maciço de células inflamatórias na mucosa/submucosa. Essas alterações foram reduzidas e a arquitetura histológica do cólon foi recuperada pelo tratamento oral com Eudragit-SBA-15-Ac2-26 (Figura 28A).

Para descrever os mecanismos envolvidos na proteção da arquitetura intestinal causada pelo tratamento com Eudargit-SBA-15-Ac2-26, a expressão de marcadores de regeneração tecidual foi realizada por imuno-histoquímica. A administração de DSS levou a uma menor expressão de claudina-1, um componente importante das junções epiteliais, essencial para a integridade da barreira intestinal; redução do marcador mucina-2, associado às células caliciformes, levando à secreção prejudicada de muco; reduziu a proliferação de células epiteliais e reduziu a quantidade de macrófagos M2 anti-inflamatórios no tecido. O tratamento oral com

Eudragit-SBA-15-Ac2-26 resgatou todos estes prejuízos na arquitetura do tecido causada pela administração do DSS (Figura 28B-E).

**Figura 28.** Histopatologia e imunohistoquímica da região proximal do cólon

(A) Escore histopatológico representado por unidades arbitrárias. As seções foram avaliadas cegamente e as alterações consideradas foram destacadas. Edema tecidual (colchetes), infiltrados inflamatórios (ponta de seta preta) e ulcerações (seta vermelha). Grupo naive apresentando histoarquitetura normal. Seções de cólon de camundongos submetidas ao IHC. (B) Seções representativas e porcentagem (%) de área marcada para marcador Claudina-1. (C) Seções representativas e número de células positivas por campo para marcador MUC-2. (D) Seções representativas e número de células positivas por corte para o marcador PCNA. (E) Seções representativas e número de células positivas por campo para o marcador CD163. n = 10 animais/grupo. Barra de escala: 50  $\mu$ m. Seções: 4  $\mu$ m. \* $p < 0,05$ , \*\* $p < 0,01$ , \*\*\* $p < 0,001$ , \*\*\*\* $p < 0,0001$  vs DSS; & $p < 0,05$ , &&& $p < 0,0001$  vs DSS + Eudragit-SBA-15.

Associados, o conjunto de dados físico-químicos da caracterização da incorporação do peptídeo ao SBA-15, da cinética de trânsito do SBA-15 *in vivo* e da liberação do peptídeo Ac2-26 tanto *in vivo* como *in vitro*, bem como da eficácia terapêutica por administração oral forneceram dados promissores para a utilização da plataforma SBA-15- Eudragit para entrega do peptídeo no intestino inflamado.

### **Análise em Organoides Intestinais: Impacto de rAnxA1 e Ac2-26 nas Junções Epiteliais**

#### ***Anxa1 aumentou TEER e suprimiu o comprometimento da integridade da barreira causado pelo tratamento com LPS***

Para avaliar o efeito da rAnxA1 nas TJs epiteliais da barreira intestinal, desenvolvemos organoides 3D baseados em células-tronco do cólon murino. Resumidamente, as células-tronco foram isoladas do cólon do camundongo através de tratamentos com colagenase e depois cultivadas como organoides 3D. Os enteroides foram, então, diferenciados em monocamadas epiteliais intestinais polarizadas que se assemelham aos diferentes tipos de enterócitos e colonócitos *in vivo* (Figura 29A). As células epiteliais polarizadas foram desafiadas com LPS para induzir o modelo intestinal inflamado e o efeito da rAnxA1 foi avaliado (Figura 29B; A50= rAnxA1. 50 ng/mL) Utilizamos duas abordagens para avaliar a permeabilidade da barreira intestinal: a resistência elétrica transepitelial (TEER) e o ensaio de permeabilização FITC-dextram. Primeiro, observamos que rAnxA1 (aumentou o TEER dos EDMs não inflamados em comparação com os não tratados (Figura 29C). Como esperado, o tratamento com LPS alterou as TJs epiteliais intestinais, levando à redução no TEER (Figura 29C, 1E) e aumento na permeabilização do FITC-dextrano (Figura 29F). Os efeitos anteriores sobre a integridade da barreira causados pelo LPS foram suprimidos e revertidos na presença de rAnxA1 (Figura 29C, 1E e 1F).

**Figura 29.** O tratamento com ANXA1 diminui a permeabilidade intestinal mediada por LPS em EDMs

(A) Fluxograma mostrando o desenvolvimento de organoides murinos 3D do cólon de camundongos. Os organoides foram divididos em células únicas que são diferenciadas *in vitro* em células epiteliais polarizadas em uma placa de 96 poços. (B) Diagrama mostrando o desenho experimental. Os EDMs polarizados foram tratados ou não com rAnxA1 (A50; 50ng/mL) e desafiados com LPS. A integridade da barreira intestinal foi avaliada por TEER, as células foram utilizadas para PCR e IF, e os sobrenadantes foram coletados para ensaios de ELISA. (C) Imagens representativas de microscopia de EDMs não tratados, EDMs desafiados com LPS, EDMs desafiados com LPS e tratados com rAnxA1 e EDMs tratados com AnxA1. A ampliação é de 20x, barra de escala de 50  $\mu$ m. (D) Alteração percentual no TEER em EDMs não tratados ou tratados com rANXA1 por 24 horas. (E) Alteração percentual no TEER em EDMs desafiados com LPS e tratados ou não com AnxA1. \* $p < 0,05$ , \*\* $p < 0,01$  conforme determinado pelo Teste *t* de Student. ### ***O tratamento com rAnxA1 modificou a transcrição das proteínas junccionais epiteliais intestinais***

Estudos anteriores relataram que ZO-1, ocludina, claudina-1 e claudina-2 são bons marcadores para TJs epiteliais intestinais no modelo EDMs (Sharma et al., 2021). Desta forma, os efeitos do tratamento com rAnxA1 na transcrição desses marcadores após o desafio com o LPS foram avaliados (Figura 30A). Como esperado, o LPS reduziu o nível de transcrição de TJs epiteliais, como ocludina e ZO-1 (Figura 30B e C), e o tratamento com rAnxA1 reverteu esses efeitos do LPS. O nível de mRNA de claudina-2 foi regulado positivamente nos EDMs desafiados por LPS e o tratamento com rAnxA1 diminuiu os níveis de mRNA para esta molécula de junção epitelial (Figura 30D). Não houve diferença significativa na transcrição de claudina 1 (Figura 30E). Em relação à proteína de junção aderente, o nível de transcrição da caderina (CDH1) foi regulado negativamente nos EDMs desafiados por LPS, que foi protegido na presença de rAnxA1 (Figura 30F). Os efeitos anteriores do LPS e AnxA1 em vários transcritos de junções epiteliais não foram correlacionados com aumento nas expressões dos receptores AnxA1: FPR1 e FPR2 (Figura 30G e H).

**Figura 30.** AnxA1 reverte as alterações mediadas por LPS na transcrição de proteínas de TJs e de junção aderente

(A) Diagrama mostrando os principais alvos do ensaio RT-qPCR. Os níveis de transcrição das proteínas TJs (ZO-1, ocludina, claudina-1 e claudina-2) e junção aderente (caderina). A expressão gênica relativa de ocludina (B), ZO-1 (C), claudina-2 (D), claudina-1 (E), caderina (F), FPR1 (G) e FPR2 (H) foi comparada em EDMs não tratadas (branco), EDMs +LPS (preto) e EDMs + LPS+ AnxA1 (azul). \*, \*\* e \*\*\*\* os valores médios de p são inferiores a 0,05, 0,01 e 0,0001, respectivamente, conforme determinado pelo Teste *t* de Student.

Em seguida, avaliamos a intensidade da coloração de ZO-1 e claudina-2 por microscopia confocal nos EDMs expostos a LPS. A intensidade do ZO-1 foi menor nos EDMs desafiados com LPS do que nos EDMs não tratados, enquanto o tratamento

com rAnxA1 aumentou a intensidade da coloração com ZO-1, confirmando os níveis de mRNA (Figura 31).

**Figura 31.** O tratamento com AnxA1 reverte o dano causado pelo LPS na proteína de integridade da barreira intestinal ZO-1

EDMs (não tratados), desafiados com LPS (LPS), desafiados com LPS e tratados com ANXA1 (LPS+A50), foram corados para ZO-1 (vermelho, e examinados por microscopia confocal). DAPI foi usado para coloração de núcleos. Imagens tiradas (40x) e barra de escala de 50 µm.

Além disso, a expressão da proteína formadora de poros, claudina-2, foi baixa nos EDMs não desafiados e aumentou após a estimulação com LPS. O tratamento com rAnxA1 reduziu a intensidade de claudina 2 nos EDMs desafiados por LPS (Figura 32). Coletivamente, os dados obtidos mostraram que o desafio com LPS mediou a ruptura das TJs epiteliais intestinais através da supressão dos marcadores de TJs (ZO-1) e aumentou o marcador claudina-2, associado ao aumento da permeabilidade da barreira, tanto na transcrição quanto na expressão da proteína (Figura 31 e Figura 32).

**Figura 32.** O tratamento com AnxA1 reverte a expressão da proteína de formação de poros na barreira intestinal Claudina-2

EDMs (não tratados), desafiados com LPS (LPS), desafiados com LPS e tratados com ANXA1 (LPS+A50), foram corados para Claudina-2 (vermelho, e examinados por microscopia confocal . DAPI foi usado para coloração de núcleos. Imagens tiradas (40x) e barra de escala de 50 μm.

### ***O tratamento com rANXA1 afetou as citocinas inflamatórias mediadas pelo LPS***

Em seguida, avaliamos o efeito do tratamento com rAnxA1 na produção de citocinas inflamatórias. O sobrenadante e lisado celular de EDMs desafiados com LPS e tratados ou não com rAnxA1 foram coletados para análises. O LPS aumentou a liberação de CXCL-1 e o nível de transcrição de MCP-1 (Figura 33A e B); e os tratamentos com rAnxA1 reverteram os efeitos anteriores. Em seguida, observamos que o tratamento com rAnxA1 aumentou o nível de transcrição de IL-10 (Figura 33C).

**Figura 33.** O tratamento com AnxA1 diminui as citocinas inflamatórias em células epiteliais

(A) O nível de CXCL-1 no sobrenadante foi medido por ELISA. (B) O nível de mRNA de MCP-1 foi medido no lisado celular por RT-qPCR bem como o de IL-10 (C). A expressão de mRNA na célula não tratada foi colocada como 1. \* p<0,05, \*\*p<0,01.

### ***O peptídeo Ac2-26 mimetizou os efeitos do tratamento com rAnxA1 no modelo EDM***

O peptídeo Ac2-26 representa o N-terminal da proteína ANXA1 e inclui 26 aminoácidos (Figura 34A). Para avaliar o efeito do Ac2-26 na integridade da barreira intestinal e na resposta inflamatória, tratamos a inflamação mediada por LPS nos EDMs com Ac2-26 e depois avaliamos o efeito do Ac2-26 na integridade da barreira intestinal. O tratamento com o peptídeo Ac2-26 reduziu significativamente a queda no TEER mediada pelo LPS (Figura 34B). O efeito anterior foi mediado pelo aumento dos níveis de transcrição de TJs e proteínas de junção aderentes (occludina, ZO-1 e caderina) e pela supressão da expressão de claudina-2 (Figura 34 C-F). Além disso, o Ac2-26 restaurou o efeito prejudicial do LPS nas junções epiteliais, aumentando a expressão e distribuição do ZO-1 (Figura 34G). Em relação ao efeito sobre a expressão gênica das citocinas, o tratamento com peptídeo Ac2-26 regulou negativamente de forma significativa a expressão de citocinas inflamatórias (CXCL-1 e MCP-1) e regulou positivamente a expressão da citocina anti-inflamatória, IL-10 (Figura 34H-J).

**Figura 34.** Ac2-26 mantém a integridade da barreira intestinal e tem efeito antiinflamatório

(A) Esquema mostrando do peptídeo Ac2-26. (B) Efeito do peptídeo Ac2-26 no TEER de EDMs desafiados ou não com LPS. A queda relativa do TEER foi calculada em relação ao TEER dos EDMs não tratados com Ac2-26, expressos como 1. O nível de mRNA de TJs e proteínas aderentes, como ocludina (C), ZO-1 (D), claudina-2 (E) e caderina (F) foi avaliado por RT-qPCR em EDMs desafiados por LPS tratados ou não com Ac2-26. A expressão gênica relativa foi calculada, em relação as EDMs desafiados com LPS, expressos como 1. (G) A integridade das EDMs foram analisadas para marcação com ZO-1 (vermelho) e DAPI (azul) foi usado para coloração de núcleos. (H) O nível de CXCL-1 no sobrenadante de EDMs desafiados com LPS e peptídeo LPS+Ac2-26 foi medido por ELISA e o valor relativo de CXCL-1 calculado. (I) O nível de mRNA de MCP-1 foi medido no lisado de EDMs

por RT-qPCR. O nível de transcrição de MCP-1 nos EDM desafiados por LPS foi expresso como 1. (J)  
O nível de mRNA de IL-10 foi medido no lisado de EDMs por RT-qPCR. \*  $p < 0,05$ , \*\* $p < 0,01$ , \*\*\* $p < 0,001$ .

# *Discussão*

O avanço no tratamento das DIIs representa uma colaboração global entre pesquisadores, considerando a complexidade da gênese da doença, natureza crônica e recorrente das enfermidades, resposta inadequada dos pacientes às farmacoterapias existentes e os sintomas físicos e psicossociais, que, associados, oneram os sistemas de saúde. A via oral é a preferida para administração de medicamentos no tratamento da DI, pois não é invasiva, permite alta adesão do paciente e flexibilidade no ajuste da dose, e entrega o medicamento diretamente na região do cólon. A nanotecnologia oferece uma alternativa inovadora de medicamentos, entre os quais os anti-inflamatórios, principalmente por possibilitar o carreamento de substâncias diretamente ao local de inflamação, evitando efeitos sistêmicos (GIRON et al., 2019; HUA et al., 2015; IRVING; VICTORIA, 2007; MUDSHINGE et al., 2011). A veiculação de moléculas de proteínas de baixo peso molecular e peptídeos não é trivial, uma vez que estas são alvos de enzimas presentes nos diferentes compartimentos do organismo (HUA, 2020; LOU et al., 2023). Considerando que as estruturas da AnxA1 e do peptídeo Ac2-26, o projeto foi idealizado para desenvolver formulações farmacêuticas para veiculação dos mesmos para o tratamento de DIIs. Demonstramos a funcionalização eficiente da AnxA1 em MLNC e a incorporação do peptídeo Ac2-26 em SBA-15, e as eficácias terapêuticas dos mesmos na colite induzida em camundongos.

As LNCs tem demonstrado alta efetividade no carreamento de substâncias e tem como principal vantagem seu alto grau de estabilidade, além de possuírem duas interfaces para alocar substâncias de diferentes características de solubilidade, sendo o núcleo capaz de alocar substâncias lipossolúveis e a superfície polimérica capaz de ancorar proteínas e outras substâncias de caráter hidrossolúvel (POHLMANN et al., 2013; VENTURINI et al., 2011). As suspensões de LNC utilizadas neste trabalho foram preparadas conforme método já descrito (JÄGER et al., 2009; MÜLLER C.R et al., 2001; VENTURINI et al., 2011), chamado deposição interfacial de polímero pré-formado. A formação da MLNC se baseia na interação eletrostática entre o grupo amônio da quitosana e grupos carregados negativamente na superfície da LNC, indicando a interação da quitosana com a lecitina na interface partícula-água (MOSQUEIRA et al., 2000; VENTURINI et al., 2011).

O potencial eletrocinético de um sistema coloidal é medido por meio do potencial zeta, o qual expressa a diferença de potencial entre o meio de dispersão e a camada estacionária de fluido ligada à partícula (RABINOVICH-GUILATT et al.,

2004). O potencial zeta pode afetar principalmente a captação celular das NPs. A membrana celular é composta de proteoglicanos sulfatados negativamente, a interação eletrostática dessa superfície celular aniônica à NPs catiônicas resulta em uma ligação altamente iônica que facilita a captação celular (SAHAY; ALAKHOVA; KABANOV, 2010; WILHELM et al., 2003).

A mudança de polaridade da LNC para a MLNC observada no potencial zeta é atribuída a interação dos componentes lecitina, composta principalmente de fosfatidilserina que apresenta característica dipolar, que interage com a quitosana, carregada positivamente. Assim, a formação da MLNC se baseia na interação eletrostática entre o grupo amônio da quitosana e grupos carregados negativamente na superfície da LNC, indicando a interação da quitosana com a lecitina na interface partícula-água (MOSQUEIRA et al., 2000; PATTNI; TORCHILIN, 2015). A principal técnica utilizada para análise do potencial zeta é o espalhamento de luz eletroforético, sendo esse parâmetro considerado um importante ponto de estabilidade de NPs em suspensão (KATHE; HENRIKSEN; CHAUHAN, 2014). Os valores observados para LNC e MLNC correspondem aos encontrados em trabalhos anteriores que utilizaram nanocápsulas revestidas com os mesmos materiais (BENDER et al., 2012; CÉ et al., 2016) e a adição de AnxA1 a nanocápsula não alterou a polaridade da mesma

Além do potencial zeta, que dita o potencial de interação de partículas com células e tecidos, o tamanho dessas partículas presentes em cada solução é outro parâmetro que ativa os mecanismos de internalização celular de NPs (BAHARI; HAMISHEHKAR, 2016; DANAEI et al., 2018; RENNICK; JOHNSTON; PARTON, 2021). Alguns nanocarreadores se acumulam em tecidos alvo ou sofrem agregação e, como consequência afeta a distribuição do tamanho das partículas ou índice de heterogeneidade na solução, identificado pelo PDI. Os valores de PDI podem variar de 0 a 1, sendo os valores próximos de 0 são considerados monodispersos e indicam que a NP terá absorção pela célula, enquanto que valores de PDI maiores que 0,7 indicam que a amostra tem uma distribuição de tamanho de partícula ampla, o que dificulta a interação com as células (STETEFELD; MCKENNA; PATEL, 2016). Os valores obtidos pela MLNC foi 0,22 e semelhante a estudos prévios que empregaram LNC, MLNC e MLNC conjugada com proteína (BENDER et al., 2014; CAVALCANTE et al., 2021; CÉ et al., 2016; DE CASTRO LEÃO et al., 2021; VENTURINI et al., 2011).

As propriedades físico-químicas da MLNC-AnxA1 proporcionaram a continuidade para os estudos *in vivo*, sendo que o primeiro objetivo seria avaliar a eficácia da MLNC-AnxA1 pela administração oral. Em trabalho prévio do nosso grupo de pesquisa, Rodrigues et al. (2016) mostrou que a LNC é resistente ao pH estomacal e de ser capaz de atravessar barreiras endógenas. Ademais, os resultados obtidos no trabalho publicado por Michalowski et al., (2020), indicavam que a estrutura supramolecular obtida pela parede múltipla e a ligação covalente da proteína ao metal seriam suficientemente robustas para proteger a Anexina A1 da degradação nos compartimentos gastrointestinais. No entanto, a administração oral de MLNC-AnxA1 não foi eficaz sobre os sintomas da colite, sugerindo que as ações *in vivo* dos componentes fisiológicos no TGI possam ter deslocado a proteína da estrutura supramolecular, com consequente inativação da AnxA1.

A nanotecnologia vem ganhando espaço na pesquisa e desenvolvimento de estratégias terapêuticas para as DII, sendo a administração realizada, principalmente, pelas vias oral ou intravenosa (GIRON et al., 2019; YANG; MERLIN, 2019). Apesar da administração via oral possuir as vantagens de ser menos invasiva e de fácil adesão a terapias, muitas vezes a via intraperitoneal é utilizada como um método alternativo à via oral para evitar a degradação de biofármacos pelo TGI e aumentar a absorção de formulações em suspensão (AL SHOYAIB; ARCHIE; KARAMYAN, 2020). Nosso estudo demonstrou que a administração intravenosa de MLNC-AnxA1 e rAnxA1 não inibiu a sintomatologia da colite induzida em camundongos, Embora, não desvendamos o que possa ter ocorrido com MNLN-AnxA1 no compartimento central, supomos que a nanocapsula utilizada não foi capaz de ser distribuída para o tecido inflamado, ou a rAnxA1 foi deslocada da MNLN e até mesmo degradada pelas enzimas plasmáticas. . No entanto, o tratamento intraperitoneal com MLNC-AnxA1 foi capaz de reduzir de forma eficiente os sintomas clínicos da doença e inibir resposta inflamatória e promover regeneração tecidual.

A administração de NPs pela via intraperitoneal pode aumentar a resposta farmacológica e reduzir a toxicidade de medicamentos em diversos casos (BRANQUINHO et al., 2017; DENG et al., 2016; MOSQUEIRA et al., 2004). A cavidade peritoneal é formada por um líquido composto de água, eletrólitos e outras substâncias provenientes do interstício. Possui uma quantidade significativa de leucócitos, sendo principalmente macrófagos, seguido de uma pequena quantidade de linfócitos do tipo B1 e B2 produtores de imunoglobulinas do tipo IgA (BAIN et al.,

2016; BLACKBURN; STANTON, 2014). Essas células são abundantes no omento, um tecido adiposo localizado logo abaixo das células mesoteliais, que recobre os órgãos peritoneais, tornando esse local ideal para gerar respostas imunológicas a antígenos ou patógenos na cavidade peritoneal (MIRONOV; GUSEV; BARADI, 1979; WILKOSZ et al., 2005). Além de possuir uma grande rede de capilares sanguíneos, vasos e nódulos linfáticos que se juntam ao sistema circulatório venoso através do ducto torácico e do ducto linfático direito, o peritônio visceral é composto por camada única de células mesoteliais escamosas com microvilosidades, que contêm grande número de vesículas pinocíticas que facilitam a absorção das moléculas (ISHIGURO et al., 2018; VAN BAAL et al., 2017).

Durante a resposta inflamatória, as células mesoteliais e estromais são responsáveis pela secreção de citocinas e quimiocinas, promovendo a quimiotaxia de leucócitos do peritônio e da circulação, com acúmulo principalmente de neutrófilos e macrófagos M1 (BÉNÉZECH et al., 2015; MEZA-PEREZ; RANDALL, 2017). Diante de uma resposta inflamatória exacerbada, característica da colite, destaca-se o incremento acentuado de citocinas e quimiocinas na parede intestinal. Essas substâncias, produzidas pelas células na lâmina própria em resposta ao dano tecidual e à invasão da microbiota residente, desencadeiam a quimiotaxia de leucócitos da circulação. Esse fenômeno, por sua vez, sugere um possível aumento do contingente de células imunes na região peritoneal. Notavelmente, os nossos dados, indicam que a eficácia do mecanismo de entrega da rAnxA1 é otimizada quando administrada intraperitonealmente por nanocápsulas, as quais podem atuar sobre células do peritônio ou sobre as células da parede intestinal. Há indícios de que essas nanocápsulas podem ser internalizadas pelas células do mesotélio visceral, agindo diretamente sobre o intestino inflamado (SINIS et al., 2018).

É importante ressaltar que a administração i.p. de todas os tratamentos MLNC; AnxA1 ou MLNC-AnxA1 inibiram o recrutamento de neutrófilos para a lâmina própria, o que não seria esperado para a MLNC, uma vez que se conhece que a AnxA1 inibe o recrutamento de neutrófilos para foco de lesão inflamado (HAYHOE et al., 2006; SUGIMOTO et al., 2016). Resultados anteriores do nosso grupo mostraram que tratamentos com LNCs contendo poli  $\epsilon$ -caprolactona apresentaram redução da capacidade migratória de leucócitos. Os resultados obtidos mostraram que os efeitos anti-inflamatórios das nanocápsulas foram dependentes da inibição da via de MAP-

quinase e da mobilização e influxo de cálcio intracelular (SANDRI et al., 2019)(SANDRI et al., 2019). Desta forma, o resultado obtido com a MLNC sugere investigações adicionais sobre a super-estrutura nanométrica sobre funções de neutrófilos. No entanto, a administração de MLNC-AnxA1 induziu a polarização de macrófagos para o perfil M2 da eferocitose, tanto in vivo quanto in vitro, induziu também a secreção de TGFbeta, e teve papel altamente benéfico na estruturação tecidual. Os resultados evocados pela LMNC-AnxA1 foram superiores ao induzido pela própria AnxA1 livre, o que demonstra que maior efetividade da foram nanaoestruturada.

A administração oral de medicamentos é considerada menos invasiva e permite alta adesão do paciente e flexibilidade no ajuste da dose. No entanto, pequenas moléculas e proteínas apresentam baixa biodisponibilidade por via oral e requerem abordagens técnicas farmacêuticas adequadas para resistir ao ambiente propício para a degradação de substâncias, uma vez que os desafios se encontram na presença de bactérias, enzimas e aos diferentes pHs no TGI (YUN; CHO; PARK, 2013). Com base nas ações benéficas robustas de AnxA1 sobre DIIs e nos resultados obtidos para o tratamento de colite experimental induzida por DSS com MLNC-AnxA1 pela via intraperitoneal, inferimos aqui que o peptídeo mimético Ac2-26 de AnxA1 poderia ser incorporado em um sistema de entrega colon-específico. Assim, o Ac2-26 foi conjugado na micropartícula de sílica mesoporosa ordenada SBA-15 e revestido com um polímero Eudragit® L30 D55, o qual apresenta resistência a pHs inferiores a 7 e poderia proteger o SBA-15-Ac2-26 dos danos indesejados do TGI para fornecer Ac2-26 na área inflamada do cólon.

A SBA-15 apresenta estrutura de alta resistência térmica, hidrotérmica e mecânica (ZHAO et al., 1998a), conferindo sua capacidade de resistir ao pH e às ações enzimáticas (MARIANO-NETO et al., 2014). Os componentes estruturais da SBA-15 contêm muitos grupos silanol essenciais (Si-OH) (ZHAO et al., 1998a, 1998b) para ligar substâncias em sua estrutura. SBA-15 também apresenta alta área superficial, grande volume de poros e distribuição de tamanho de nanoporos e mesoporosos, em torno de 10 nm. Juntas, essas propriedades permitem o transporte seguro de pequenas moléculas através do TGI (LU et al., 2010; MECHLER-DREIBI et al., 2021a; ROSENHOLM; SAHLGREN; LINDÉN, 2010; SARKAR et al., 2023; SCARAMUZZI et al., 2011; XU; LEI; YU, 2019). De fato, através da modelação dos dados SAXS, em combinação com os resultados do NAI, foi possível concluir que

grande parte do peptídeo Ac2-26 adicionados é carregada nos mesoporos de SBA-15. Em contraste, a concentração remanescente está, de alguma forma, na superfície da sílica, cenário semelhante ao observado em estudos anteriores nos quais os autores carregaram proteínas, em vez de peptídeos (LOSITO et al., 2021; TREZENA et al., 2022). Conforme sugerido por Rasmussen et al. (2019), em estudo que avaliou o potencial da SBA-15 como veículo para a anatoxina diftérica (dANA), focalizando sua aplicação em vacinas orais. Os resultados indicaram que a estrutura da dANA permaneceu estável após o processo de secagem. A liberação no ambiente intestinal mimético em pH 6,8, monitorada por SAXS, foi gradual, com destaque após 6 horas. A imunização oral de camundongos com SBA-dANA resultou na produção significativa de anticorpos específicos, destacando o SBA-15 como um adjuvante promissor para vacinas orais. Essa abordagem sugere uma plataforma viável para o desenvolvimento eficaz de vacinas orais e macroporosidade SBA-15 são capazes de proteger o conteúdo biológico adsorvido frente a condições ambientais adversas, como o TGI.

Pela indicação de que havia Ac2-26 na superfície da sílica, SBA-15-Ac2-26 foi revestida com Eudragit®, um copolímero aniônico responsivo ao pH produzido a partir de metacrilato de metila e ácido metacrílico. Apresenta características de solubilidade dependentes do pH, permanecendo estável sob condições ácidas, mas dissolvendo-se em pH básico (pH > 7,0) para facilitar a liberação do medicamento, que em condições fisiológicas pode começar na porção íleo distal (THAKRAL; THAKRAL; MAJUMDAR, 2013). Eudragit é um carreador de medicamento eficiente em pH ácido, pois carrega carga negativa significativa permitindo sua absorção preferencialmente em locais de inflamação (BARBOSA et al., 2019; HOLMÉN LARSSON et al., 2009; LI et al., 2020). A análise da tomografia de imagem corroborou que o Eudragit-SBA-15 administrado por via oral permaneceu no TGI por um período prolongado, adequado para a entrega de medicamentos ao intestino. Além disso, a absorção de Eudragit-SBA-15 pelas células epiteliais intestinais *in vitro* em modelos celulares bidimensionais ou tridimensionais foi deficiente, reforçando a hipótese de que o SBA-15 não é absorvido no intestino e pode ser excretado pelas fezes (ZHAO et al., 1998a). Dados adicionais abordaram o Eudragit-SBA-15 como uma plataforma adequada para entregar o peptídeo no intestino, já que Ac2-26 foi detectado no epitélio (células Caco-2) após incubação *in vitro* com SBA-15-Ac2-26, e Eudragit-SBA-15 entregou Ac2-26 no intestino após administração oral.

Os efeitos benéficos do Ac2-26 na sintomatologia da DII estão relacionados à sua ligação ao FPR1 no epitélio inflamado (LEONI et al., 2013, 2015b)(Leoni 2013; Leoni 2015). Ainda, o Ac2-26 atua como AnxA1, ligando-se a ambos os receptores para promover efeitos anti-inflamatórios e reparo tecidual (COORAY et al., 2013). É muito bem estabelecido que o Ac2-26 liga-se a FPR2 em neutrófilos e macrófagos, inibindo o desenvolvimento de inflamações inatas e facilitando a resolução do processo (DALLI et al., [s.d.]; RÜGER et al., 2020; ZHENG et al., 2023). Nas DIIs, AnxA1 é expressa e liberada por neutrófilos e macrófagos na lâmina própria e medeia a eferocitose via ligação ao receptor FPR2 (DE PAULA-SILVA et al., 2016, 2021). Com base nos conceitos bem estabelecidos do Ac2-26 na inflamação e na DII, bem como na distribuição do Ac2-26 in vivo após administração oral da Eudragit-SBA-15-Ac2-26 no intestino, podemos supor que o tratamento promoveu efeito benéfico de forma rápida, detectados pela acentuada redução da perda de peso 24 horas após o primeiro tratamento, que se manteve nas três administrações seguintes uma vez ao dia durante a fase de recuperação da doença.

A eficácia do tratamento oral da colite não pôde ser comparada à administração livre de Ac2-26 devido à baixa biodisponibilidade dos peptídeos por ingestão oral (LANGGUTH et al., 1997). No 10º dia de doença, o tratamento inibiu o influxo de neutrófilos e monócitos no tecido inflamado e reduziu os níveis de citocinas pró-inflamatórias secretadas no tecido. Este último efeito poderia refletir o menor número de células inflamatórias. Os níveis da citocina anti-inflamatória e pró-resolução IL-10 foram aumentados pelo tratamento e podem ser relacionados à alta quantidade de macrófagos CD163, marcador de macrófagos M2, no tecido dos camundongos tratados. De fato, o Ac2-26 apresenta efeito semelhantemente a AnxA1, limitando o tráfego de macrófagos e neutrófilos para locais inflamados (GIROL et al., 2013b; HAYHOE et al., 2006; LIM; PERVAIZ, 2007) e inibe a secreção de citocinas pró-inflamatórias pelas vias transcricional e pós-transcricional (REISCHL et al., 2021b; WALTHER; RIEHEMANN; GERKE, 2000).

Ac2-26 é um peptídeo de resolução reconhecido, que polariza macrófagos M2 e induz a apoptose de neutrófilos para eferocitose adicional por macrófagos (GIROL et al., 2013b; HAYHOE et al., 2006; LI et al., 2019b; LIM; PERVAIZ, 2007; MCARTHUR et al., 2020b; REISCHL et al., 2021b). Nossos resultados corroboram outro estudo que utilizou o tratamento local de NPs de PLGA-Colágeno IV como carreadores do peptídeo Ac2-26 via intra mucosal e observaram resposta clínica

semelhante ao nosso, além de aumento da regeneração tecidual e redução da resposta inflamatória promovendo resolução da inflamação de forma mais rápida após uma única injeção da nanopartícula de Ac2-26 (LEONI et al., 2015; REISCHL et al., 2021). Ainda, a entrega alvo-específica utilizando as características químicas do órgão também foram utilizadas por Li et al., (2019). Ao utilizar o revestimento polimérico sensível a ROS, visto que altas concentrações de ROS são encontradas em sítios inflamatórios, o tratamento com NPs contendo Ac2-26 apresentou resultados anti-inflamatórios promissores similares aos encontrados em nosso trabalho.

A complexidade dos mecanismos celulares e moleculares da regeneração tecidual nas DII envolve uma ampla diversidade de alvos como marcadores do processo. Optamos por quantificar o perfil de células imunes na lâmina própria, a expressão de moléculas de junção epitelial (*tight junctions* - TJ) e marcadores de proliferação celular. Macrófagos são células amplamente identificadas em todos os tecidos do organismo e possuem uma grande plasticidade celular, permitindo alterar seu fenótipo dependendo do microambiente e da fase da infamação (MOSSER; EDWARDS, 2009). O aumento da resposta anti-inflamatória induzida tanto por MLNC-AnxA1 quanto SBA15-Ac2-26 foi observado em nossos resultados, com o aumento do número celular de macrófagos M2 anti-inflamatórios na lamina própria. Esse resultado sobre a polarização de macrófagos *in vivo* corroborou os efeitos anti-inflamatórios já elucidados para a AnxA1 e reforçam a importância dessa proteína no controle da resolução da inflamação (MCARTHUR et al., 2020; MORAES et al., 2017).

Os resultados obtidos para o experimento de polarização de macrófagos utilizando células primárias obtidas de medula de camundongos demonstraram que MLNC-AnxA1 proporcionou aumento na porcentagem de macrófagos com fenótipo M2 (CD206+), bem como o aumento da produção de TGF $\beta$ , ambos resultados indicativos de resposta anti-inflamatória. Embora, mostramos que o tratamento com MLNC-AnxA1 polarizou os macrófagos de M1 para M2, nos surpreendemos com o fato de a AnxA1 não apresentar esse efeito. A literatura abrange diversos trabalhos que demonstram esse papel para a proteína, como mencionado anteriormente. No entanto, quando observadas as concentrações utilizadas, nos deparamos com concentrações muito maiores do que a por nós utilizada. Como visto no trabalho de McArthur et al. (2020) que utilizou 10 nM para polarizar macrófagos, quando comparado ao nosso estudo, que utilizou 500 ng/mL, que resultou em solução 0,075

nM de AnxA1, podemos concluir que a encapsulação da AnxA1 otimizou a resposta da proteína em macrófagos em concentração muito menor do que as utilizadas na literatura (LI et al., 2011; LOCATELLI et al., 2014; XU et al., 2021), sendo este dado inédito para a MLNC e AnxA1 e demonstra a importância de integrar a nanotecnologia com a farmacologia, como visto reduzindo a utilização de compostos e obtendo-se resultados farmacológicos consistentes (ZHANG et al., 2018).

As TJ são proteínas responsáveis por controlar a polarização de células epiteliais e endoteliais, bem como a sua formação morfológica e funcional, controlando a permeabilidade paracelular por meio da seletividade de carga e tamanho das moléculas em contato. O conjunto de proteínas que formam esse eixo celular pode ser dividido em proteínas transmembrana e citosólicas. Zonula Occludens-1 (ZO-1) é uma proteína TJ citosólica reguladora e essencial para a polimerização de outra TJ, a Claudina 1. A homeostasia gastrointestinal é dependente da função dessas proteínas, e alterações no ZO-1 afetam a expressão e funções de outros TJ. Portanto, níveis dinâmicos estáveis dessas proteínas são fundamentais para o funcionamento normal da barreira epitelial (HOROWITZ et al., 2023; UMEDA et al., 2006). Ambos tratamentos com MLNC-AnxA1 e SBA15-Ac2-26 interferiram na expressão das junções epiteliais. A expressão de ZO-1 foi reduzida no epitélio de camundongos com colite induzida por DSS, sendo essa expressão recuperada a níveis normais após o tratamento com MLNC-AnxA1. Esse resultado pode estar associado também a composição da MLNC a qual contém quitosana em sua estrutura. A administração oral de doses mais elevadas de do polissacarídeo quitosana durante a fase resolutiva da inflamação melhorou a recuperação dos parâmetros clínicos e histológicos, incluindo a expressão de ZO-1 (SOMMER et al., 2021).

A Claudina 1, desempenha um papel relevante na homeostase intestinal, devido a sua localização transmembranar nas células epiteliais intestinais (ČUŽIĆ et al., 2021; POPE et al., 2014). Em nosso modelo de colite, a expressão de Claudina 1 foi reduzida e localizada no epitélio danificado do grupo de camundongos DSS. Os tratamentos com MLNC-AnxA1 e SBA15-Ac2-26 recuperaram a expressão de claudina-1 no tecido, especialmente em criptas reorganizadas. Portanto, os dados aqui mostrados evidenciam que tanto a AnxA1 quanto Ac2-26 liberados pela MLNC e SBA-15, respectivamente, promovem a expressão de proteínas TJ sendo capaz de reestabelecer a estrutura da cripta.

Efetivamente, a ação fisiológica da AnxA1 sobre as junções celulares foi evidenciada em células endoteliais da barreira hematoencefálica, conforme demonstrado por Cristante et al. (2013). Nesse cenário, a deficiência na expressão dessa proteína está associada à origem de doenças neurodegenerativas. É relevante destacar que, em situações assim, o tratamento agudo com rAnxA1 foi capaz de restaurar a expressão das junções celulares, contribuindo para a redução do desenvolvimento de doenças cerebrais. Além disso, evidenciou-se que o tratamento *in vitro* com rAnxA1 resulta no aumento da expressão de Claudina 1 e ZO-1 no epitélio uterino durante a fase de fixação dos blastocistos (HEBEDA et al., 2020). Associados, estes dados sustentam a AnxA1 como uma proteína essencial para a estabilização das TJ, e aqui mostramos, pela primeira vez, o efeito da AnxA1 funcionalizada no rearranjo das TJs no epitélio intestinal durante a colite. Explorando os efeitos promissores da AnxA1 na expressão de TJ, buscamos uma abordagem para elucidar o papel da AnxA1 e de seu peptídeo mimético Ac2-26 de forma específica sobre células epiteliais intestinais. Para evitar a interferência do sistema imune, optamos por empregar o modelo 2D de monocamada derivada de enteróides. Esse modelo, também denominado “intestino em placa de cultura”, é capaz de mimetizar a barreira intestinal devido a capacidade de diferenciação celular das células-tronco adultas, as quais são utilizadas para o desenvolvimento de organóides.

Vários mecanismos estão associados à perda da barreira intestinal, como diminuição da expressão de TJs e proteínas de junção aderente, mudança na expressão de claudinas e modulação do citoesqueleto (LECHUGA; IVANOV, 2017). O mecanismo de mudança de expressão de claudina ocorre pela regulação positiva de claudinas formadoras de poros no epitélio inflamado, especialmente a claudina 2 (IVANOV; NAYDENOV, 2013). A regulação positiva de claudina 2 é identificada em vários cenários de inflamação intestinal e proporciona o aumento da permeabilidade da barreira (SAHOO et al., 2021; WEI et al., 2021; ZHANG et al., 2013). O aumento da permeabilidade intestinal leva à translocação de bactérias e endotoxinas (LPS) através da mucosa danificada para a circulação, causando inflamação sistêmica (LECHUGA; IVANOV, 2017; LI et al., 2023). A presença de LPS no intestino e na circulação ativa várias vias de sinalização por meio da ligação do receptor TLR4-4 e da estimulação do fator de transcrição NF- $\kappa$ B, levando à liberação de citocinas inflamatórias (FITZGERALD et al., 2003). Neste estudo, desafiamos os EDMs com

LPS para induzir a ruptura de TJ nas camadas epiteliais, como mostrado por um aumento na queda de TEER e na permeabilização do dextrano FITC nos EDMs desafiados por LPS ao longo do tempo. A ruptura na integridade da barreira intestinal pode ter ocorrido pela diminuição na expressão de ocludina, ZO-1 e caderina e a um aumento na expressão da proteína TJ formadora de poros, claudina 2. Os tratamentos AnxA1 e Ac2-26 reverteram todos os efeitos prejudiciais mediados por LPS sobre as EDMs expostos. Estas descobertas sugerem que AnxA1 e Ac2-26 têm um efeito protetor direto no epitélio intestinal, afetando a transcrição de várias proteínas de junção epitelial.

Em seguida, avaliamos o efeito de AnxA1 e Ac2-26 nas citocinas inflamatórias liberadas pelas células epiteliais após estímulo inflamatório. Para este fim, avaliamos o nível de CXCL-1 e MCP-1 como as principais citocinas pró-inflamatórias liberadas pelas células epiteliais intestinais no modelo intestinal 2D [Sayed et al., 2020a; Sayed et al., 2020b]. AnxA1 e Ac2-26 reduziram as citocinas pró-inflamatórias mediadas pelo LPS e aumentaram o nível da citocina anti-inflamatória IL-10. Embora os linfócitos e macrófagos sejam as principais fontes de IL-10 no intestino, as células epiteliais também secretam IL-10 (NGUYEN; ALJAMAEI; STADNYK, 2021).

A IL-10 atua sobre as células epiteliais intestinais e contribui para vários papéis na homeostase intestinal, como regular a liberação de citocinas, para manter a integridade da barreira intestinal e promover a tolerância do epitélio e afetar as ações celulares (Nguyen et al., 2021). Curiosamente, a IL-10 é uma citocina importante para a barreira intestinal e o TEER, uma vez que regula a expressão das TJs, principalmente reduzindo a expressão de claudina 2 (ZHENG et al., 2017), aumentando a expressão da junção de adesão E-caderina e do componente dos desmossomos, desmogleína 2 (XUE et al., 2016). Nossos dados *in vivo* em modelo de colite experimental já indicavam a relação da AnxA1 e IL-10, no entanto em um microambiente com a presença de células imunes. Estudos anteriores mostraram que os efeitos anti-inflamatórios de AnxA1 e Ac2-26 são decorrentes, principalmente, de ações em células do sistema imunológico, incluindo a diminuição da migração de células do sistema imunológico para a área inflamada e o aumento da apoptose dos neutrófilos (LEONI; NUSRAT, 2016; PERRETTI; D'ACQUISTO, 2009a). Como já salientado, as ações anti-inflamatórias da AnxA1 são mediadas pelos receptores e FPR1 e 2 presentes nas membranas celulares. Aqui, relatamos que um possível efeito anti-inflamatório de Anxa1 e Ac2-26 é mediado pelas células epiteliais.

A reorganização epitelial que ocorre na fase de regeneração tecidual na colite experimental é dependente de vias de sinalização de proliferação celular, alterações morfológicas e diferenciação celular. PCNA e Ki67 são proteínas nucleares envolvidas nesses procesos. PCNA participa das vias de síntese e reparo de DNA, enquanto Ki67 está envolvido na proliferação celular e na transcrição de RNA ribossômico (MROUJ et al., 2021; RANDALL-DEMLLO et al., 2016). Corroborando a reorganização das criptas visualizadas em animais tratados com MLNC-AnxA1, foi também observado aumento da proliferação celular na região da base da cripta intestinal, região essa onde estão localizadas as células células-tronco e as células em diferenciação, e constituem um centro de sinalização fundamental para a formação da barreira celular intestinal (HSU; LI; FUCHS, 2014). Além disso, o tratamento com AnxA1 funcionalizado por MLNC reduziu a proliferação de células que se estende a região apical. Este efeito é observado no crescimento desorganizado e células proliferadas em aproximadamente dois terços do comprimento da cripta podem ser indicativos de displasia celular (JURÍKOVÁ et al., 2016; RANDALL-DEMLLO et al., 2016). O tratamento com SBA15-Ac2-26 proporcionou o aumento do número de células positivas para PCNA. Apesar da distribuição das células PCNA+ ocorrer de forma desorganizada, percorrendo a cripta em direção a parte apical, a combinação desse resultado com a histologia, o escore histológico e os sintomas clínicos do grupo tratado com SBA15-Ac2-26 indicam proliferação não associada a displasia e sim a regeneração tecidual. No entanto, para confirmar essa hipótese seria necessário a utilização de outro marcador de proliferação celular.

A formulação da nanocápsula de PCL é considerada biocompatível e biodegradável (POHLMANN et al., 2013), no entanto, alguns de seus compostos podem interferir em funções celulares e alterar a resposta celular fisiológica, promovendo efeitos tóxicos (IVANOV, 2008). O ensaio de MTT, o qual avalia a função mitocondrial, foi utilizado como teste de triagem para viabilidade e demonstrou que as concentrações (3) e (4) de MLNC e MLNC-AnxA1 (Tabela 3), após incubação de 48 horas apresentam atividade mitocondrial inferior a 75%. A citotoxicidade observada pode estar relacionada a alguns componentes da estrutura da nanocápsula, como o surfactante Tween 20. Como observado em um trabalho realizado por Eskandani et al. (2013) que utilizou o MTT para avaliar o crescimento celular, o Tween 20 foi capaz de reduzir o crescimento de células HUVEC e A549 de forma concentração

dependente, além de causar danos ao DNA, fragmentação de cromatina e induzir as células a apoptose. Outro trabalho avaliando a citotoxicidade de LNCs sobre células Raw 264.7, identificou que o componente surfactante com funç emulsificantes e solubilizantes, Solutol®, presente na estrutura da nanocápsula, também causava efeitos tóxicos, sendo que este foi o único componente identificado como tóxico, e quando testada a LNC completa (contendo o surfactante), não foram observados efeitos tóxicos quando comparado com o surfactante isolado (LE ROUX et al., 2017).

De acordo com as características do sistema coloidal empregado no presente trabalho, a análise de citotoxicidade por um método colorimétrico que utiliza a dispersão de luz, como o MTT, não é considerada a melhor alternativa para análise. Além disso, o resultado pode estar associado a alteração do metabolismo mitocondrial, e não a ausência de viabilidade diretamente (DE CRISTO SOARES ALVES et al., 2020; STEPANENKO; DMITRENKO, 2015). Células viáveis e com membranas celulares integras apresentam um conjunto de enzimas denominadas esterases que atuam de forma eficiente. Dessa forma, outra alternativa para análise direta de viabilidade é a marcação com calceína. Por se tratar de um método bem padronizado na literatura, apresenta alta sensibilidade. Essa substância incolor reage com as esterases, que removem os grupos éster e tornam a molécula fluorescente, ficando retida no citoplasma celular de células integras (BRATOSIN et al., 2005; LICHTENFELS et al., 1994). Foi observado que o tratamento com MLNC ou MLNC-AnxA1 reduziu o a porcentagem de células viáveis após 48 horas, diferentemente da AnxA1 que não causou toxicidade. Os resultados observados demonstraram que a toxicidade de MLNC e MLNC-AnxA1 na maior concentração de partículas apresenta diferença significativa na porcentagem de células em necrose após 48 horas de tratamento. Esse resultado corrobora com outros estudos que utilizaram a nanocápsula de PCL e observaram aumento de apoptose e necrose quando comparados os grupos MLNC contendo anticorpos em relação ao anticorpo livre (BRUINSMANN et al., 2020; DE CRISTO SOARES ALVES et al., 2020). Esse resultado sugere que o efeito tóxico encontrado no ensaio de morte celular é relativo a nanocápsula, e não a AnxA1.

A citotoxicidade de SBA-15 é extensivamente reportada pela literatura em diferentes tipos celulares, dentre eles a célula epitelial intestinal Caco-2 e células endoteliais HUVEC. Ainda, as concentrações utilizadas nesses estudos são pelo menos quatro vezes maiores do que as utilizadas em no presente trabalho (ALMÁŠI et

al., 2020; HEIKKILÄ et al., 2010; ZHAO et al., 2021). Nossos resultados demonstraram que 50 ng/mL de SBA-15 não apresentou efeitos tóxicos para macrófagos e células Caco-2 (dados não apresentados) sendo concentração de SBA-15 testada foi baseada nas concentrações de Ac2-26 utilizadas na literatura.

As NPs podem interagir de diferentes formas com células do sistema imune e serem captadas por diferentes mecanismos de endocitose de acordo com o tipo celular estudado e as características físico-químicas da NP utilizada (FARACE et al., 2016; GILLERON et al., 2013). A capacidade de internalização ou captação de NPs pelas células é o principal critério a ser levado em consideração antes da sua utilização *in vivo*, em especial o diâmetro e o PDI atributos a nanocarreadores lipídicos, que podem alterar a internalização celular, estabilidade, eficiência do encapsulamento, o perfil de liberação do medicamento, a biodistribuição e a mucoadesão (AZHAR; BAHARI; HAMISHEHKAR, 2016). Sabe-se que o *uptake* celular ocorre de forma quase exclusiva via endocitose, que é o processo de transporte ativo de materiais para o interior da célula. Esse processo ocorre principalmente por (1) endocitose dependente de clatrina e dinamina, (2) endocitose independente de clatrina, mas dependente de dinamina para endocitose rápida conduzida por ligante de proteínas de membrana específicas, (3) endocitose independente de clatrina e dinamina, (4) macropinocitose e (5) fagocitose.

Nosso resultado demonstrou que MLNC foi internalizada por macrófagos após 2 horas de tratamento, no entanto MLNC-AnxA1 necessitou de um tempo superior, sugerindo que a presença da proteína AnxA1 em sua estrutura possa estar alterando o mecanismo de endocitose, sendo necessário um tempo superior a 2 horas de tratamento para internalização. Esse resultado corrobora outros estudos que utilizaram LNC e observaram *uptake* da nanocápsulas em diferentes tipos celulares, como células de melanoma e endoteliais (DREWES et al., 2017b; PEREIRA et al., 2018; SANDRI et al., 2019). Ainda, um estudo realizado por Cavalcante et al. (2016), utilizando células Raw 264.7 tratadas com a MLNC funcionalizada com anticorpo reportou internalização celular após 3 horas de tratamento, corroborando nosso resultado o qual demonstrou ser necessário um tempo superior a 2 horas para a endocitose da MLNC-AnxA1. O estudo também avaliou os mecanismos de endocitose das NCs e concluiu que o mecanismo responsável pela internalização das NCs ocorre por meio de pinocitose, principalmente via macropinocitose e com pequena

participação de vias dependentes de dinamina. Por se tratar da mesma NC utilizada em nosso trabalho e também possuir uma proteína em sua camada polimérica, sugere-se que a MLNC-AnxA1 foi internalizada por mecanismo semelhante. No entanto, estudos utilizando bloqueadores de endocitose são necessários para confirmar essa hipótese.

Usualmente partículas com tamanho superior a 500 nm são internalizadas via fagocitose (MORENO-MENDIETA et al., 2022). De acordo com os resultados obtidos para as análises físicas de SBA-15, investigamos o mecanismo de captação dessas partículas por macrófagos J774A.1 e Raw 264.7. Macrófagos foram capazes de internalizar SBA-15 após 4 horas de incubação, sendo esse resultado mais proeminente em 24 horas. A fagocitose foi confirmada como mecanismo responsável pela internalização da SBA-15 pela pré-incubação das células com o inibidor de fagocitose, citocalasina B. Ainda, nossos resultados demonstraram baixa internalização de SBA-15 sobre células epiteliais intestinais, resultado este confirmado pelos modelos de EDM e citometria de fluxo (dados não apresentados). Esse resultado corrobora a literatura que descreve a SBA-15 como um veículo para liberação rápida de substâncias, sendo sua absorção intestinal baixa (LI et al., 2015; ZHAO et al., 1998a).

Apesar da baixa internalização de SBA-15 por células epiteliais intestinais, nossos resultados demonstraram que o Ac2-26 foi propriamente liberado, sendo detectado tanto em macrófagos quanto células Caco-2. Este resultado sugere que a SBA-15-Ac2-26-Eud pode ser considerada um veículo promissor para o tratamento da colite, oferecendo um mecanismo eficaz de liberação local do peptídeo. Essa descoberta destaca o potencial terapêutico dessa formulação no contexto do tratamento da colite, abrindo caminho para investigações mais aprofundadas e desenvolvimento clínico.

# *Conclusões*

Os resultados obtidos no presente trabalho revelam que as plataformas MLNC e SBA-15 desenvolvidas foram eficazes para a incorporação de rAnxA1 (92%) e Ac2-26 (88%) em MLNC e SBA-15, respectivamente. A funcionalização do MLNC demonstrou ser uma ferramenta eficaz para a entrega, via intraperitoneal, de moléculas hidrofílicas, oferecendo ações anti-inflamatórias e pró-resolução na reparação de tecidos danificados nos distúrbios intestinais. A reversão dos sintomas da colite experimental, associados a recuperação tecidual, ressaltou o potencial terapêutico da micropartícula SBA-15 revestida por polímero pela via oral. Embora ambas as abordagens apresentem resultados experimentais promissores, é crucial salientar a necessidade contínua de investigações mais aprofundadas para avaliar integralmente os riscos e benefícios dessas estratégias terapêuticas para doenças inflamatórias intestinais.

**CERTIFICADO**

Certificamos que a proposta intitulada **Efeitos da nanocápsula de núcleo lipídico contendo anexina A1 em modelo de colite ulcerativa induzida em camundongos**, registrada com o nº 598, sob a responsabilidade do(a) pesquisador(a) **Milena Fronza Broering**, sob orientação da **Profa. Dra. Sandra Helena Poliselli Farsky** – que envolve produção ou manutenção ou utilização de animais pertencentes ao filo Chordata, subfilo Vertebrata (exceto humanos), para fins de pesquisa científica – encontra-se de acordo com os preceitos da Lei Federal nº 11.794, de 8 de outubro de 2008, do Decreto Federal nº 6.899, de 15 de julho de 2009, e das normas editadas pelo Conselho Nacional de Controle de Experimentação Animal (CONCEA), e foi aprovada pela Comissão de Ética no Uso de Animais (CEUA) da Faculdade de Ciências Farmacêuticas da Universidade de São Paulo (FCF/USP), em reunião de **04 de outubro de 2019**.

Finalidade	Pesquisa Científica
Vigência da autorização	04/10/2019 a 28/02/2022
Espécie/linhagem/raça	<b>Camundongo C57BL/6 WT</b>
Número de animais	<b>84</b>
Sexo	Macho
Peso/Idade	6-10 semanas – 20-25g
Origem	Biotérios UNIFESP

### ABSTRACT

Inflammatory bowel diseases are debilitating illnesses characterized by severe inflammation of the gastrointestinal tract. Treatments currently available are expensive and ineffective. We here investigated the role of red-light emitting diode (LED) on dextran sodium sulfate (DSS)-induced colitis. DSS was added to the drinking water of male mice at days 0, 2, 4 and withdrawn at day 6. LED irradiation was performed daily for 90s from day 6 to 9 on the right and left sides of the ventral surface and beside the external anal region. LED treatment decreased the amount of crypt dysplasia/adema, inflammatory infiltrate and ulcers, attenuated apoptosis and increased proliferation of crypt cells. Also, LED treatment induced expression of annexin A1 in the damaged epithelium, preserved the organization of claudin-1 and skewed cytokine profiling towards a more anti-inflammatory status. Thus, LED treatment promotes structural protection and modulates the inflammatory response, constituting a potential non-invasive and low-cost combined therapy to help patients achieve disease remission.

### 1. Introduction

Inflammatory bowel diseases (IBDs) are illnesses characterized by severe gastrointestinal inflammation leading to debilitating symptoms, such as abdominal pain, bloody diarrhea and pronounced loss of body weight [1]. From 1990 to 2016, the highest prevalence of IBDs worldwide was reported in the United States and Europe, but the incidence in emerging countries from Africa, Asia and South America has also increased. In 2017, IBDs affected 1.6 million people in the United States alone, representing a great burden to public health care [2].

The pathogenesis of IBDs emerges from a multifactorial background. Genetically predisposed individuals when exposed to environmental factors, such as unhealthy diet, smoking, pollution, hygiene conditions, intake of drugs, among others, suffer a loss of gut epithelial barrier function, compromising its tolerogenic relationship with gut microbiota [3,4]. As a result, the translocation of microorganisms to the intestinal tissue activates and recruits inflammatory cells to the injured site. This inflammatory infiltrate is characterized mainly by T lymphocytes, macrophages and neutrophils. T cells induce interferon-gamma (IFN- $\gamma$ )-mediated proinflammatory actions. Macrophages secrete IL-6 and tumor necrosis factor-alpha (TNF- $\alpha$ ), which prevent apoptosis of

lymphocytes and induce macrophage activation and immune cell recruitment/transmigration, amplifying the inflammatory response. Neutrophils, once in the infiltrated tissue, release IL-6, IL-1 $\beta$  and TNF- $\alpha$  [4,5]. Together, all these effects sustain inflammation and halt tissue repair. Counter-regulatory mechanisms involve actions of endogenous pro-resolution mediators; however, anti-inflammatory mechanisms are often insufficient to halt the progression of this inflammatory process, which then leads to chronic tissue damage [6].

The two main types of IBDs - ulcerative colitis (UC) and Crohn's disease (CD) - have similar symptomatology, but they can compromise distinct regions of the gastrointestinal tract and affect its histoarchitecture differently [7]. Due to the complexity of these illnesses, some patients can show mixed symptoms and misleading histopathological features, compromising diagnosis; the condition of these patients can even be diagnosed as unclassified-IBD, making the choice of correct therapies difficult [8].

After diagnosis, IBD patients are usually subjected to a "step-up" therapeutic approach; treatment strategies start with amino salicylates, which are then substituted by corticosteroids, followed by immunosuppressants and finally by biological therapies should the previously used drugs cause adverse effects, fail to induce remission or the

## 1. Introduction

Inflammatory bowel diseases (IBDs) are illnesses characterized by severe gastrointestinal inflammation leading to debilitating symptoms, such as abdominal pain, bloody diarrhea and pronounced loss of body weight [1]. From 1990 to 2016, the highest prevalence of IBDs worldwide was reported in the United States and Europe, but the incidence in emerging countries from Africa, Asia and South America has also increased. In 2017, IBDs affected 1.6 million people in the United States alone, representing a great burden to public health care [2].

The pathogenesis of IBDs emerges from a multifactorial background. Genetically predisposed individuals when exposed to environmental factors, such as unhealthy diet, smoking, pollution, hygiene conditions, intake of drugs, among others, suffer a loss of gut epithelial barrier function, compromising its tolerogenic relationship with gut microbiota [3,4]. As a result, the translocation of microorganisms to the intestinal tissue activates and recruits inflammatory cells to the injured site. This inflammatory infiltrate is characterized mainly by T lymphocytes, macrophages and neutrophils. T cells induce interferon-gamma (IFN- $\gamma$ )-mediated proinflammatory actions. Macrophages secrete IL-6 and tumor necrosis factor-alpha (TNF- $\alpha$ ), which prevent apoptosis of

lymphocytes and induce macrophage activation and immune cell recruitment/transmigration, amplifying the inflammatory response. Neutrophils, once in the infiltrated tissue, release IL-6, IL-1 $\beta$  and TNF- $\alpha$  [4,5]. Together, all these effects sustain inflammation and halt tissue repair. Counter-regulatory mechanisms involve actions of endogenous pro-resolution mediators; however, anti-inflammatory mechanisms are often insufficient to halt the progression of this inflammatory process, which then leads to chronic tissue damage [6].

The two main types of IBDs - ulcerative colitis (UC) and Crohn's disease (CD) - have similar symptomatology, but they can compromise distinct regions of the gastrointestinal tract and affect its histoarchitecture differently [7]. Due to the complexity of these illnesses, some patients can show mixed symptoms and misleading histopathological features, compromising diagnosis; the condition of these patients can even be diagnosed as unclassified-IBD, making the choice of correct therapies difficult [8].

After diagnosis, IBD patients are usually subjected to a "step-up" therapeutic approach; treatment strategies start with amino salicylates, which are then substituted by corticosteroids, followed by immunosuppressants and finally by biological therapies should the previously used drugs cause adverse effects, fail to induce remission or the

patient becomes unresponsive after a long-term use. Ultimately, patients suffering from severe disease that do not respond to any medication undergo surgical procedures, but their quality of life is permanently reduced [1,9,10]. All such therapeutic failures contribute to a scenario of pharmacoeconomic overwhelming that can cost the patient up to US\$ 26,555 just in the first year after diagnosis [11]. For these reasons, it is urgent to propose novel therapeutic strategies that can either achieve disease remission faster or prolong remission periods while also being cost-effective so more individuals can benefit from them [12].

In the last few years, studies have demonstrated the beneficial effects of photobiomodulation therapy on cellular and molecular processes [13–15]. In humans, it is already used for aesthetic purposes to sustain morphological cutaneous homeostasis and has already been demonstrated to be safe [16]. Nowadays, different lasers and low-level light therapies emitting wavelengths in the spectrum of the visible light have been emerging as potential options to treat a diversity of human diseases, including neurodegenerative disorders [17]. Based on recent successful studies in humans and on a plethora of results obtained in experimental animals, several clinical trials have been already proposed aiming to investigate the role of photobiomodulation on treatment of human disorders [18,19]. Recently, our group demonstrated the beneficial effects of LED treatment on experimental models of pulmonary inflammatory diseases, decreasing neutrophil influx and secretion of pro-inflammatory cytokines in the inflamed tissue [15] while also promoting secretion of pro-resolving mediators that favor tissue homeostasis [13].

Therapies able to induce early resolution of inflammation and tissue recovery can dramatically improve the quality of life of IBD patients. Here, we provide evidence that LED therapy protects intestinal histoarchitecture by preserving epithelial tight junctions, stimulating the expression of proliferative and resolutive mediators and attenuating inflammatory responses. These benefits of LED treatment, accompanied by a low-cost and ease of manipulation, allow us to suggest it can be combined with other therapies in order to help patients more easily achieve disease remission.

## 2. Methods

### 2.1. Animals

Male C57BL/6 wild-type (WT) mice, aged 8–10 weeks and weighting 20–25 g were bred under pathogen-free conditions in the Faculty of Pharmaceutical Sciences of the University of São Paulo. Animals were kept in a 12-h light/dark cycle at temperatures ranging from 20 to 25 °C while having access to water and feed ad libitum. All experiments were performed in accordance with Brazilian laws of animal ethics; this study was approved by the Ethics Committee of Animal Use of the Faculty of Pharmaceutical Sciences of the University of São Paulo (CEUA/FCF/USP), protocol n° 596.

### 3. Colitis Model and LED Treatment

Mice were divided into four groups ( $n = 5$  animals/group): Control, LED, DSS and DSS + LED. Control groups (Control and LED) received autoclaved water with no additives, while colitic groups (DSS and DSS + LED) received autoclaved water containing Dextran Sulfate Sodium (DSS, MW 40,000, Dextran Products Limited, Canada) at a concentration of 2%. DSS solutions were replenished every two days (Days 0, 2 and 4) so DSS received by the animals would be uniform. DSS was withdrawn on Day 6; up to Day 10, mice received water with no additives.

Between days 6 and 9, healthy and DSS treated mice (LED and DSS + LED, respectively) were irradiated with red LED during 90 s on both right and left sides of the ventral surface and beside the external anal region. Control and DSS groups were handled the same way as

LED-treated animals but with the LED emitting device turned off in order to standardize exposure stress among groups.

The parameters of LED irradiation were chosen based on earlier studies (Costa et al. 2017), described as follows:

Wavelength	Potency	Energy density	Potency density	Area	Total energy	Time
660 nm	100 mW	5 J/cm <sup>2</sup>	33.3 mW/cm <sup>2</sup>	2.8cm <sup>2</sup>	15 J	90s

Clinical parameters (body weight, diarrhea and rectal blood) were observed and registered daily and the Disease Activity Index (DAI) was calculated from the sum of these parameters. On day 10, animals were euthanized after inhalation of isoflurane anesthetic (2-chloro-2-(difluoromethoxy)-1,1,1-trifluoroethane). The colon was removed from the ileocecal junction up to the proximity of the anus, washed and macroscopically evaluated (weight and length). Finally, the colon was fragmented for histological (distal colon), enzymatic and protein (mid/proximal colon) analyzes.

### 4. Histopathological Analysis

Samples from the distal portion of the colon were fixed in 4% paraformaldehyde for 24 h, dehydrated in graded ethanol, cleared in xylene and embedded in paraffin for histopathological and immunohistochemical analyses. For histopathological analysis, 5 µm sections were stained with hematoxylin and eosin (EasyPath) and analyzed using a high-power objective (40×) on an AxioCam coupled to a Zeiss microscope (Carl Zeiss, Jena, Germany).

### 5. Immunohistochemical Staining and Analysis

Colon sections were deparaffinized, hydrated and incubated with sodium citrate buffer (pH 6.0) at 96 °C for 30 min for antigen retrieval. Endogenous peroxidase activity was blocked with 3% hydrogen peroxide used for three 10 min rounds. Next, blocking of unspecific binding sites was carried out with 10% BSA diluted in Tris-buffer saline (TBS) for one hour. Then, sections were incubated with anti-AnxA1, anti-claudin-1, anti-PCNA or anti-ZO antibodies overnight at 4 °C. Sections were then washed and incubated with a secondary antibody conjugated with HRP (1 h, room temperature). The staining was detected using 3,3'-diaminobenzidine (DAB substrate; Invitrogen, USA). Finally, sections were counterstained with hematoxylin and mounted.

**Quantification of proliferative nuclei.** Five fields of the mucosal layer from PCNA-stained sections were photographed using a 40× high-power objective and the number of positive nuclei was quantified for each field assessed. Results were expressed as mean ± S.E.M. of proliferative nuclei.

### 6. TUNEL Assay

TUNEL staining was used to reveal apoptotic cells in tissues. Positive cells were detected using in situ Apoptosis Detection Kit (Abcam), according to manufacturer's instructions.

### 7. Quantification of Tissue Myeloperoxidase

The amount of neutrophils and macrophages infiltrated in the colonic tissue was indirectly measured by myeloperoxidase (MPO) colorimetric assay as previously described (de Paula Silva et al., 2016). Briefly, fragments from the middle colon were homogenized in a 5% EDTA/NaCl buffer (pH 4.7) with the aid of a homogenizing apparatus (Ultra-turrax) and centrifuged at 10,000 rpm at 4 °C for 15 min. The tissue pellet was resuspended in a 0.2% NaCl, 1.6% NaCl-5% glucose

and 0.5% hexadecyl trimethyl ammonium bromide (pH 5.4) solution. The samples were then frozen in liquid nitrogen and thawed at 37 °C three times. Finally, 50 µL of the supernatants were incubated with tetramethylbenzidine at 1:1 (TMB, Millipore, USA) and MPO activity was measured at 450 nm using a spectrophotometer. Results were expressed as mean ± S.E.M. of the optical density (O.D.) corrected by the weight of each sample (O.D./mg).

#### 8. Quantification of pro-and Anti-Inflammatory Mediators in the Intestinal Tissue

Proximal colon samples were homogenized in RIPA buffer containing 0.1% of a protease inhibitor solution using an ultra-turrax apparatus. Next, samples were centrifuged at 12,000 rpm at 4 °C for 10 min. Cytokines (IFN-γ, IL-1β, IL-6, IL-10 and TNF-α) were analyzed from the supernatants by ELISA according to manufacturer's instructions (BD Biosciences). The concentrations obtained in pg/mL were corrected by the total amounts of protein of each sample, as measured by Bradford assay.

##### 8.1. Statistical Analysis

Kolmogorov-Smirnov test was used to determine whether distributions of data sets were parametric or non-parametric. Then, one-way ANOVA tests followed by Tukey's (parametric) or Dunn's post-test (non-parametric) were carried out to compare differences between means. Probability values of  $p < 0.05$  were considered statistically significant and results were expressed as mean ± SEM.

#### 9. Results

##### 9.1. LED Therapy Attenuates Disease Activity and Gut Alterations Induced by DSS

DSS administration was effective in inducing colitis; animals had higher DAI values characterized by increased weight loss, diarrhea, occult blood in feces and colon shortening (Fig. 1). LED treatment was initiated at Day 6, when the disease was at the peak of its course, and was carried out up to Day 9, spanning the chronification phase of the model. Data obtained showed LED treatment did not improve weight loss, diarrhea and fecal blood parameters individually, (Fig. 1A-C) but this treatment significantly reduced disease activity index at Day 8 (Fig. 1D) and prevented loss of colonic structure integrity (Fig. 1E-G). It is worthy mentioning that LED treatment, in healthy animals, did not cause any alterations in the parameters mentioned above.

##### 10. LED Therapy Promotes Histological Recovery by Stimulating Epithelial Renovation

The significant effect of LED therapy on large intestine anatomy suggests it can induce recovery responses in the damaged tissue. Indeed, LED treatment protected colonic histoarchitecture during colitis, decreasing the frequency of crypts dysplasia/edema and reducing inflammatory infiltrates and ulcerations in comparison with non-treated mice (Fig. 2A-D). Possible mechanisms that could explain these interesting effects on epithelial protection were assessed by staining using Proliferating Cell Nuclear Antigen (PCNA) (Fig. 2F-I) and Terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) (Fig. 2K-O) to determine, respectively, proliferation and apoptosis.

PCNA is a 36 kDa acidic non-histone nuclear protein that allows DNA polymerase to initiate leading strand DNA replication and, as proliferating cells remain longer in G1-S phase, is also a marker of proliferation [20]. As expected, PCNA was normally expressed at the base of intestinal crypts of control mice, where undifferentiated cells are constantly proliferating to renovate the epithelial barrier (Fig. 2F). TUNEL assay did not reveal an evident staining of apoptotic cells in

these mice (Fig. 2K). However, healthy animals treated with LED showed PCNA immunostained nuclei also in the migratory region of glands (Fig. 2G) and a more pronounced TUNEL staining in apical barrier cells (Fig. 2L), indicating that LED treatment by itself stimulates epithelial renovation. Similarly to LED-treated mice, DSS mice showed PCNA-positive cells throughout the extension of the glands (Fig. 2H), indicating that the damaged tissue is being induced towards recovery; however, this effect is not enough to fully revert the extensive ulcerations resulting from cell apoptosis at the apical epithelium (Fig. 2M). DSS + LED mice showed a significant increase in proliferative epithelial cells throughout the extension of the glands compared to untreated mice (Fig. 2I-J) and epithelial apoptosis was not detected (Fig. 2N). These effects contributed to preservation of the epithelial barrier.

Finally, both DSS and DSS + LED mice showed increased MPO activity in the colon, indicating these tissues have more infiltrated neutrophils and macrophages [21]. When relativized by MPO levels, the number of TUNEL-positive phagocytes in the colon of colitic mice was higher after LED therapy (data not show).

##### 11. LED Therapy Induces Expression of Proteins Related to Integrity of Epithelial Structure

Epithelial integrity is maintained by the interaction of anchoring molecules expressed in cell-cell and cell-membrane interfaces, which not only allows physical binding, but also signaling of intracellular pathways which control the necessary cell metabolism responsible for keeping such epithelial integrity [22]. Based on our previous data, claudin-1 and zonula occludens-1 (ZO-1) were assessed via immunohistochemistry; these proteins are pivotal paracellular molecules in the intestinal barrier. No differences regarding ZO-1 and claudin-1 expressions were observed between groups (Fig. 3A-E and F-J, respectively). However, the structural organization of claudin-1 was altered by DSS, which became irregularly distributed throughout the extension of epithelial cells (Fig. 3H - detail). Mice treated with LED showed preserved claudin-1 organization in the epithelial barrier (Fig. 3I), evidencing LED treatment acts specifically on control of claudin-1 organization rather than on its expression.

Annexin A1 (AnxA1) is an anti-inflammatory and pro-resolutive protein expressed and secreted by epithelial and inflammatory cells. In the same manner as PCNA, AnxA1 is expressed in the epithelial barrier of mice undergoing DSS-induced colitis and is linked to homeostatic mechanisms which involve wound closure and down-regulation of inflammatory responses [23]. It has been fully demonstrated that colitis is aggravated in AnxA1-knockout mice [25]. In colitic mice treated with LED, higher expression of AnxA1 was detected in epithelial cells at damaged areas (Figs. 3K-3N, 3O) and increased overall expression in tissue homogenates was confirmed by ELISA (Fig. 3P), suggesting this could be another mechanism of tissue repair induced by LED therapy.

##### 12. LED Therapy Induces Expression and Secretion of Cytokines Responsible for Tissue Recovery

Further quantification of cytokines secreted by gut tissue contributed towards a better understanding of the link between disease stage and actions of LED therapy. Although TNF-α levels are very low in the tissue of DSS mice (Fig. 4A), increased levels of IL-1β and IL-6 (Figured 4B-4C) and reduced levels of IL-10 (Figured 4D) indicate active disease. LED therapy attenuated the inflammatory process by preventing the increase of IL-1β and IL-6 levels caused by DSS (Figured 4B-4C) and accelerated its resolution by markedly increasing IFN-γ and TGF-β levels (Figs. 4E-4F).

#### 13. Discussion

IBDs are debilitating diseases of complex pathogenesis and it often takes time after initial diagnosis for proper individualized therapeutic

approaches to be decided upon. The currently available therapies are cost-intensive and pose great burdens to health care systems [11]. Here we demonstrate the beneficial actions of a non-invasive, low-cost LED therapy on a DSS-induced colitis model, focusing on its promising protective actions on the epithelial barrier.

IBDs are autoimmune diseases heavily influenced by both environment and immune/genetic background of patients [4]. Although DSS-induced colitis as a model does not address all intrinsic characteristics of IBDs genesis, it is a useful experimental tool used to determine the efficacy of novel therapies in a complex organism affected by intestinal inflammation. DSS causes lesions in the intestinal epithelium allowing translocation of microbiota components into the underlying tissue, which then initiates an immune response leading to tissue damage [26].

In our model, DSS induced clinical manifestations equivalent to those observed in IBD patients, and LED treatment at days 7–9 of the disease had a subtle but certain protective role, considering especially intestinal morphology. Intestine shortening and reduction of intestinal weight are common occurrences in DSS-induced colitis [26]; although there are no final explanations in scientific literature as to what exactly causes such severe anatomical changes, it is known that intestinal length in humans is correlated with body weight [28]. Thus, it is possible to suggest that loss of body weight decreases intestinal length, which is accompanied by a decrease of intestinal weight, as we here demonstrate. Also, the intestine damaged by inflammation initiates a response towards homeostasis that involves tissue remodeling; in this process, intestinal cells can either accumulate or degrade extracellular matrix (ECM)

components on its walls, which could evolve to either fibrosis or structural rupture [25]. As these events impact intestinal anatomy and function, the protection exerted by LED therapy upon intestine weight might be a consequence of a more complex beneficial effect on gut structure and could play a role on clinical improvement.

Indeed, further histological data corroborated the effects of LED treatment on tissue recovery, as it increased proliferation of epithelial cells and prevented their apoptosis, contributing to wound closure. Downregulating inflammatory responses is another strategy to protect the epithelial barrier, as the accumulation of inflammatory cells and mediators in the damaged site prolongs tissue injury [3]. Our research group had previously demonstrated LED therapy decreases MPO activity in bronchoalveolar lavage in an acute lung injury model in mice [27]. Here, LED treatment did not affect MPO activity, but slightly increased apoptosis of transmigrated phagocytes (data not shown). Although the number of apoptotic neutrophils/macrophages corrected by MPO levels for each mouse of the DSS + LED treated group was not statistically significant when compared to the DSS group, this is evidence that at the final day of the experimental model LED therapy starts the resolution of the immune response. This process protects the epithelial barrier from further damage and helps ceasing the translocation of microbiota components to the intestinal tissue, attenuating disease progression [25].

Alongside epithelial cell death, disruption of tight junctions constitutes an important mechanism linked to epithelial barrier damage [30]. Claudin-1 belongs to a family of 26 proteins and composes the backbone of tight junction strands in simple epithelial cells, directly controlling their barrier functions [31]. Claudin-1 is down-expressed in

myeloid differentiation protein 2 knockout mice, and when these mice are subjected to DSS-induced colitis, the disease develops in a more severe manner than in wild-type strains [32]. Furthermore, several pharmacological approaches aimed at treating IBDs induce the expression of claudin-1, resulting in an improvement of epithelial barrier integrity in UC patients [33,34]. Claudin-1 also activates intracellular signaling pathways that include metalloproteinase-9 and p-ERK, activating Notch-signaling and leading to epithelial proliferation [34]. In the present investigation, we observed immunostaining for Claudin-1 was “unorganized” in the DSS group, while LED treated mice showed a strong and more spread immunostaining. We also detected a higher expression of AnxA1 in the epithelial barrier of DSS + LED mice compared to DSS mice. AnxA1 is a 37 kDa phospholipid binding protein expressed by inflammatory and epithelial cells under a diversity of stimuli, and this mediator exerts pivotal control on the development of the innate immune response, on resolution of inflammation and on tissue repair [35]. Existing evidence on the role of AnxA1 in IBD experimental models is robust. AnxA1 is highly expressed by epithelial cells during the resolution phase of disease, and clinical symptoms of colitis are worse in AnxA1 knockout mice than in WT animals [25,36]. In biopsies from CD patients, decreased expression of AnxA1 is correlated with inflammatory activity and poor response to anti-TNF- $\alpha$  treatments [37]. Also, in the sera of UC patients, increased amounts of secreted AnxA1-containing extracellular vesicles were detected, suggesting the release of AnxA1 in vesicles constitutes a systemic manner of activating wound repair responses [24]. In the cells that compose the blood-brain-barrier (BBB), endogenous AnxA1 regulates cytoskeleton structure and stabilizes tight junctions, being expressed at higher levels

Fig. 3. Expression of tissue integrity-related proteins in the epithelial barrier of DSS-induced colitis mice treated with LED. (A–D and E) ZO-1 localization and expression. (F–I and J) Claudin-1 localization (white arrows) and expression. (K–N and P) AnxA1 localization (black arrows) and tissue levels. (O) Reaction control.  $n = 3$  mice/group. Sections: 3  $\mu\text{m}$ . Bars: 20  $\mu\text{m}$  (A, B, D; E, F, H, I, J, L), 50  $\mu\text{m}$  (C, G, K). Counterstaining: Hematoxylin. \*\*  $p < 0.01$  vs Control; §§  $p < 0.01$ .

in cell-cell contact sites [38]; indeed, AnxA1-knockout mice show decreased organization of tight junctions in these same structures [39]. Our data indicate the increased expression of AnxA1 induced by LED therapy in epithelial cells might have a potential effect on claudin-1 organization during DSS-induced colitis.

Besides its structural functions, AnxA1 also plays several roles as an anti-inflammatory and pro-resolutive mediator. This protein was first described as an inhibitor of phospholipase A2 activity in cell membranes, impairing the production of lipid pro-inflammatory mediators [40]. Up-regulation and down regulation of pro- and anti-inflammatory mediators are, respectively, hallmarks of colitis. Here, we observed the intestinal tissue collected from LED treated mice produced lower amounts of IL-1 $\beta$  and IL-6 while producing higher levels of IFN- $\gamma$ . The later effect is unexpected as IFN- $\gamma$  is an important mediator for the pathogenesis of IBDs [3,41]. However, IFN- $\gamma$  also plays a role in the resolution of colitis by evoking the expression of the IL-10 receptor on intestinal epithelium and inducing the polarization of anti-inflammatory macrophages [42]. Other investigations have pointed out the roles of IFN- $\gamma$  in inhibiting leukocyte transmigration into inflamed lung tissue and in limiting inflammation at injured sites [43]. We have already showed LED treatment on an acute lung injury model induced by LPS increases the levels of IFN- $\gamma$  in bronchoalveolar lavage [29]. Hence, the increased secretion of IFN- $\gamma$  emerges as a potential pro-resolutive mechanism of action promoted by LED therapy and, at later phases of colitis, might contribute to anti-inflammatory effects and tissue reorganization. Finally, LED treatment increased the levels of TGF- $\beta$ , a down-modulator of mucosal inflammation and promoter of

epithelial repair [43]. Interestingly, levels of TNF- $\alpha$  and IL-10 were low and equivalent in all groups of animals studied, suggesting that these cytokines do not play a relevant role at Day 10 of DSS-induced colitis model in mice.

IBDs are complex processes characterized by secretion of a plethora of proteins by a diversity of cells, which exert pleiotropic actions and can exert either deleterious or benefic actions on different phases of the disease. Targeting a specific cell or mediator not always leads to conclusive results. Data here obtained demonstrate the beneficial actions of LED therapy on the intestinal mucosa damaged by DSS. Due to its non-invasive delivery and low-cost applicability, LED therapy and its anti-inflammatory effects might be used as promising tools to be combined with other drugs in order to accelerate remission in IBD patients.

**Abstract:** Hematopoiesis is a complex and intricate process that aims to replenish blood components in a constant fashion. It is orchestrated mostly by hematopoietic progenitor cells (hematopoietic stem cells (HSCs)) that are capable of self-renewal and differentiation. These cells can originate other cell subtypes that are responsible for maintaining vital functions, mediate innate and adaptive immune responses, provide tissues with oxygen, and control coagulation. Hematopoiesis in adults takes place in the bone marrow, which is endowed with an extensive vasculature conferring an intense flow of cells. A myriad of cell subtypes can be found in the bone marrow at different levels of activation, being also under constant action of an extensive amount of diverse chemical mediators and enzymatic systems. Bone marrow platelets, mature erythrocytes and leukocytes are delivered into the bloodstream readily available to meet body demands. Leukocytes circulate and reach different tissues, returning or not returning to the bloodstream. Senescent leukocytes, specially granulocytes, return to the bone marrow to be phagocytized by macrophages, restarting granulopoiesis. The constant high production and delivery of cells into the bloodstream, alongside the fact that blood cells can also circulate between tissues, makes the hematopoietic system a prime target for toxic agents to act upon, making the understanding of the bone marrow microenvironment vital for both toxicological sciences and risk assessment. Environmental and occupational pollutants, therapeutic molecules, drugs of abuse, and even nutritional status can directly affect progenitor cells at their differentiation and maturation stages, altering behavior and function of blood compounds and resulting in impaired immune responses, anemias, leukemias, and blood coagulation disturbances. This review aims to describe the most recently investigated molecular and cellular toxicity mechanisms of current major environmental pollutants on hematopoiesis in the bone marrow.

**Keywords:** environmental pollutants; xenobiotics; hematopoiesis; myelotoxicity

### 1. Hematopoiesis Overview

#### 1.1. Hematopoiesis and Hematopoietic Hierarchy

Hematopoiesis is a continuous, albeit complex, process that aims to generate blood cell subtypes in a steady manner. Hematopoietic stem cells (HSCs) represent a small population of pluripotent, self-renewing cells responsible for initiating the renewal of blood cells by giving rise to other cell progenitors. In humans, such cells are CD34<sup>+</sup>CD38<sup>-</sup> [1].

In bone marrow (BM), HSCs initially give rise to multipotent progenitors (MPPs), which can also be considered pluripotent. These cells have limited self-renewal capabilities, yet possess full-lineage differentiation potential [2]. These cells remain mostly quiescent at the G0 phase of the cell cycle [2,3].

but through signaling mediated by intrinsic and extrinsic factors, this population initiates cell cycle entry and starts differentiating [4,5]. MPPs give rise to common myeloid precursors (CMPs) and lymphoid precursors (CLPs) through cytokine signaling and the activation of several transcription factors [6]. MPPs differentiated into CLPs originate lymphocytes and natural killer cells that rely mainly on activation of PU.1, Ikaros and GATA-3 transcription factors [7]. Soluble factors such as IL-7 and its receptor (CD127) actively participate in CLP maturation and development, as IL-7 and CD127 deficiencies disrupt production of B and T cells. On the other hand, MPP fate-decision differentiation into CMP, which originates granulocyte-macrophage (GMP) and megakaryocyte-erythrocyte progenitors (MEPs), is modulated by PU.1 and GATA-1 [7–9].

GMP differentiation is dependent on secretion of granulocyte-macrophage-colony-stimulating factor (GM-CSF), after which macrophage-colony-stimulating factor (M-CSF) modulates the differentiation of monocytes/macrophages and granulocyte-colony-stimulating factor (G-CSF) modulates the differentiation of neutrophils, basophils, and eosinophils; the latter in a process known as granulopoiesis. MEP, under erythropoietin modulation (EPO), initiates erythropoiesis originating erythrocytes and, under thrombopoietin (TPO) effects, MEP originates megakaryocytes and platelets [6,10]. During erythropoiesis, MEP differentiates into burst-forming unit erythroid (BFU-E) and, finally, into colony-forming unit erythroid (CFU-E); this whole process is tightly modulated by soluble mediators such as erythropoietin (EPO), stem cell factor (SCF), and IL-3 and -6. At a molecular level, activation of GATA-1, STAT-5, and Kruppel-like factor-1 (KLF-1) pathways ensures that erythroid differentiation and maturation take place. Disruption of these molecular pathways leads to anemia and myeloproliferative syndromes [6,11,12].

### 1.2. HSC Quiescence

The functionality of HSCs depend on the balance between quiescence and activation. Reduced ability of HSCs to leave quiescence results in insufficient blood cell production; on the other hand, greater amounts of HSCs leaving quiescence or failing to return to quiescence after activation exhaust the HSC pool, leading to BM failure, which favors the onset of malignant diseases [13,14]. Proper response by hematopoietic progenitors to regulatory stimuli and adequate control of cell-signaling pathways that culminate in controlling DNA damage are essential for avoiding exhaustion of the HSC pool [15].

Quiescent HSCs eventually become senescent and lose the ability to proliferate. The fine-tuning between proliferative, quiescent, and senescent cells is vital for the homeostasis of the hematopoietic environment [16]. In specific areas of BM, approximately 80% of HSCs remain quiescent throughout an average human lifespan, ensuring their “stemness” when needed. HSCs can leave quiescent states and become proliferative in a transient manner in response to external stimuli, such as injuries or infections, then become quiescent again [17]. The modulation of proliferation, differentiation, and migration capabilities of HSCs is essential for control of their quiescence. The hematopoietic microenvironment is fundamental for such regulation, fine-tuning the balance required for overall homeostasis [13].

### 1.3. HSC Niches

HSCs are spatially distributed in BM in highly organized niches composed of several cell subpopulations that maintain HSC quiescence. Interactions with several stromal adjacent cell populations such as fibroblasts, osteoblasts, macrophages, and endothelial cells, in addition to the actions of soluble factors released by these cell groups, ensure the preservation of the HSC pool and modulate proliferation and quiescence of these cells [18].

A significant amount of HSCs is also associated with sinusoidal endothelial cells, from where they are able to readily enter the peripheral blood [19,20]. The release of these cells into the bloodstream and their subsequent migration and return to BM are physiological processes pivotal for homeostasis [21,22].

HSCs are located both in the endosteal and vascular niches. The endosteal niche is a complex structure that includes several components, such as progenitor and stromal cells, growth factors,

and extracellular matrix molecules that participate in the regulation of hematopoiesis [23]. The endosteal niche is interposed between the bone and BM, and includes bone-forming osteoblasts and bone resorption osteoclasts alongside other cells, such as fibroblasts, macrophages, and endothelial cells located near the endosteum [23,24]. The anatomical location of the endosteal niche also supports the modulation of HSCs, as the endosteum provides a microenvironment containing low levels of oxygen, which is an important factor for HSC quiescence [25]. Osteoblastic cells present in the endosteal niche secrete chemical mediators that activate cell signaling cascades and regulate HSCs [26,27]. The secretion of TPO and angiopoietin (Ang-1) leads to the expression of adhesion molecules in HSCs ( $\beta$ 1-integrin and *N*-cadherin) and increases quiescence of these cells [26,27]. Osteoblasts also secrete Notch receptor ligands and soluble Jagged factors; the activation of Notch receptors in HSCs inhibits differentiation of these cells and increases their self-renewal capacity under either stress or physiological conditions [27,28].

In the vascular niche, hematopoiesis occurs in the extravascular spaces between the sinuses. The medullary vascular sinuses are lined with endothelial cells and are surrounded by adventitious cells, also called CXCL12 abundant reticular (CAR) cells [29]. CAR cells are the major producers of cytokines that modulate HSC behavior, such as CXCL12 and SCF [29]. The proximity between sinusoidal endothelial cells and HSCs is very important for the maturation of the latter and, therefore, for the hematopoietic process [30]. The vascular niche is essential for the production of factors essential for the mobilization, homing, and engraftment of HSCs. The interaction between mature cells and the vascular niche is required for the release of these cells into the bloodstream. The expression of adhesion molecules by endothelial cells, such as vascular cell-adhesion molecule-1 (VCAM-1), associated with chemokine factors, mediates the maturation of megakaryocytes and the release of platelets into the bloodstream [31].

BM shelters several populations of progenitor cells other than HSCs that are essential for homeostasis, such as mesenchymal stem cells (MSCs). These cells provide a supportive microenvironment for HSCs and display high regenerative capabilities with a therapeutic potential, arising from several cell lines such as adipocytes, chondrocytes, and osteocytes [32]. The therapeutic effects associated with paracrine mechanisms linked to MSCs are extremely complex and include diverse cytokines and growth factors as well as other related receptors and signaling molecules with a wide range of biological functions [33]. MSCs and their derivatives are also essential for maintaining hematopoiesis, and for the maturation of hematopoietic lineages [34,35].

Endothelial progenitor cells (EPCs) can also be found in BM; EPCs and HSCs share hemangioblasts as common progenitors [36]. EPCs are recruited in response to ischemia and initiate angiogenesis, leading to the formation of new blood vessels, connecting fibronectin, and forming colonies and/or colony-forming units [37,38]. EPCs resemble embryonic angioblasts, which are anchorage-independent cells capable of proliferating, migrating, and differentiating into mature ECs [39]. EPCs express mainly cluster of differentiation 34 (CD34) and fetal liver kinase 1 (FLK1), although other markers have also already been identified, such as vascular endothelial growth factor receptor 2 (VEGFR2) and CD146 [40]. EPC mobilization into the bloodstream occurs depending on different disease conditions, such as tumor and cardiovascular disorders, and is mediated by a plethora of chemical mediators, with VEGF being the most well-known [41].

A schematic overview of HSC niches is illustrated in Figure 1A.

**Figure 1.** Schematic overview of HSC niches and fate-decision of hematopoietic lineages during hematopoiesis, along with the major transcription factors and cytokines involved. (A) HSC niches comprise endosteal and vascular regions containing several cell types. In the endosteal niche, osteoclasts and osteoblasts, as well as other cell types, support the vascular niche where mesenchymal stromal cells (MSCs), hematopoietic stem cells (HSCs) and CXCL12-abundant (CAR) cells are anchored. The maturation of hematopoietic lines is modulated by the fine balance between both niches. (B) Hematopoietic stem cells (HSCs) can undergo either apoptosis or senescence after suffering oxidative stress or DNA damage, which might or might not activate apoptotic pathways. Under physiological status, activation of GATA-1 and PU.1, low levels of reactive oxygen species (ROS), and modulation exerted by soluble factors such as IL-3, SCF, TPO and G-CSF in HSCs give rise to common myeloid progenitors (CMPs), which then originate neutrophils, eosinophils, basophils and monocytes. On the other hand, common lymphoid progenitors (CLPs), under influence of IL-7, are modulated by the activation of GATA-2, Ikaros, and PU.1. CMPs originate erythrocytes and platelets after the maturation of intermediary precursors, and CLPs mature into B and T lymphocytes and natural killer cells.

#### 1.4. HSC Mobilization

The recruitment of hematopoietic stem cells and progenitors (HSPCs) from BM into peripheral blood is a process known as mobilization that occurs either under physiological or stressful conditions, such as acute inflammation and chemotherapy [42,43]. Mobilization occurs based on the interplay between HSPCs and BM niche components, as well as resulting from the interaction between chemokines and their receptors. Adhesion molecules, proteases, and activation of intracellular signaling pathways also play roles in cell mobilization [42].

Indeed, the inactivation of stromal cell-derived factor-1 (SDF-1) and interleukin-8 (IL-8) alongside the enzymatic actions of proteases such as elastase, cathepsin G, and metalloproteinases (MMP-2 and MMP-9) modulate the SDF-1/C-X-C receptor 4 (CXCR4) axis and promote the release of BM-resident progenitor cells to peripheral tissues [44,45]. The SDF-1/CXCR4 axis is crucial for the maintenance, retention, and mobilization of HSPCs under homeostatic conditions or after an injury [46], as HSPCs that express CXCR4 are attracted to the highly expressing SDF-1 endosteal niche. Also, upregulation of adhesion molecules such as vascular cell adhesion molecule-1 (VCAM-1), very late antigen 4 (VLA-4), and leukocyte function antigen 1 (LFA-1) are important for the retention of HSPCs in BM; in turn,

downregulation of these molecules and of other chemokines is closely related to the mobilization of progenitors into the bloodstream [42].

HSPCs are endowed with a great therapeutic potential and, as with most of BM transplants, rely on the use of HSPCs isolated from peripheral blood after the mobilization of progenitors has been induced. The modulation of the aforementioned mechanisms mobilizes HSPCs, and this practice is widely used in clinical practice [47]. G-CSF is one of the most effective mobilizing agents [47], and repetitive G-CSF stimulation accelerates myeloid hematopoiesis, enhancing HSPC motility and migration into peripheral areas of the body [45]. Also, G-CSF induces the release of proteases, cathepsin G, and MMP-9, which downregulate levels of adhesion molecules, favoring the mobilization of HSPCs [48].

Increased release of progenitor cells and mature leukocytes from BM is part of the immune response leading to inflammatory processes. Depending on the severity of the inflammatory response, immature cells are also delivered into the bloodstream [49]. A broad range of molecules such as leukotrienes, resolvins, annexin A1, cytokines, and chemokines, among others, are involved in modulating inflammation and returning HSPCs to BM [50–53]. After an injury, such as exposure to radiation, stromal cells in BM release high amounts of SDF-1, which is responsible for inducing homing and modulating the repopulation capabilities of HSPCs [54].

### 1.5. DNA Damage, ROS Generation and Hypoxia in the Control of HSC

The mechanisms underlying the transformation of normal cells into malignant phenotypes are not yet fully understood. In order to better understand such mechanisms, the cell cycle of hematopoietic cells has been extensively investigated, as aging processes are closely linked to the accumulation of DNA damage and telomerase shortening in quiescent cells [4,55]. Such accumulated DNA damage in quiescent HSCs leads to the activation of DNA repair mechanisms only when these cells leave the G0 phase of the cell cycle; failures of DNA repair machineries, however, allow such accumulation of genomic damage to deregulate further cell cycle processes, and this is a key mechanism for leukemogenesis [15,56,57]. Still, in order to avoid malignant changes and to sustain homeostasis, hematopoietic progenitors are capable of tolerating some DNA damage due to protective mechanisms, such as DNA translesion synthesis (TLS) [58,59].

The accumulation of DNA damage and the insufficient activation of repair mechanisms leads to the exhaustion of progenitors, driving them to senescence or apoptosis. Activation of apoptotic pathways in HSCs aims to avoid a proliferation of compromised cells that have suffered irreparable DNA damage, preventing the development of malignancies. The main pro-apoptotic factor activated is the tumor suppressor protein p53. Activation of p53 leads to quiescence via activation of its downstream effector and cell cycle inhibitor p21, causing damaged cells to cease proliferation and become senescent [60,61]. Induction of apoptosis is linked to pathways involving BAX, NOXA, and PUMA in addition to activation of the ASPP1 protein, a p53 cofactor that selectively promotes or inhibits p53-mediated apoptosis. The process of controlling apoptosis and activation of HSCs, while complex, is crucial for preserving the HSC pool [61–63].

DNA damage also activates other protective intracellular mechanisms, such as autophagy. Autophagy is a catabolic process marked by the lysosomal degradation of damaged organelles and proteins, and is essential for maintaining hematopoiesis and HSC differentiation and quiescence by suppressing cell metabolism [64–66]. In response to stressors, HSCs induce autophagy to prevent cell death, mitigate the increase of reactive oxygen species (ROS) levels and promote activation of DNA repair machineries [67,68]. Mice lacking the autophagy related gene 7 (*atg7*) are more susceptible to oxidative stress, accumulation of DNA damage and loss of function of HSCs after irradiation [69].

Much like apoptosis, generation of ROSs also plays a protective role and induces autophagy. However, oxidative stress, when excessive, becomes one of the main causes of DNA damage. Excessive production of ROSs and the resulting imbalance of enzymatic mechanisms that constitute redox signaling leads to oxidative stress, resulting in oxidative-induced damage [70]. Uncontrolled ROS production is responsible for damaging DNA and macromolecules such as lipids and proteins [71,72].

Several studies associate high levels of ROS and oxidative damage as factors for the initiation and progression of hematological diseases, such as leukemias [73–76]. Still, ROS generation is essential for the functionality and modulation of HSC phenotypes and their progenitors, as the generation of ROSs regulates the self-renewal and differentiation of adult stem cells [77]. At low levels, ROSs ensure that precursors remain pluripotent, but at excessive levels, ROSs can impair the functionality of these populations, even leading to BM failure under extreme circumstances [78,79].

Aiming to avoid excessive oxidative stress, antioxidant proteins act quickly in the face of high levels of ROSs. Among them, superoxide dismutase (SOD), catalase, and glutathione peroxidase are the most important; reduced glutathione (GSH), which also exists in the cell in its oxidized form (GSSG), is perhaps the most abundant of enzymatic antioxidants [80,81].

The enzymatic machinery responsible for keeping ROS levels low in hematopoietic progenitor cells is also aided by the microenvironment of hematopoietic niches [25,78]. As the generation of ROSs is closely linked to oxygen demand, several transcription factors are involved with the regulation of low levels of oxygen in HSCs. Hypoxia-inducible factor 1 (HIF-1) is the main transcription factor responsible for allowing cells to adapt to low oxygen levels; the expression of its inducible subunit, HIF-1 $\alpha$ , is linked to the maintenance of ROSs at homeostatic levels. Lacking activity of HIF-1 $\alpha$  in progenitor cells leads to the exacerbated generation of ROS, culminating in increased cell proliferation and loss of self-renewal capacity [82,83]. Activation of fork-head O transcription factor (FoxO) subunits also plays a crucial role in keeping low the levels of ROSs in HSCs, thus playing a protective role upon oxidative stress. The deletion of heterodimers of the FoxO's family in hematopoietic cells substantially decreases the number of HSCs, leading to increased cell cycle activation, and this effect appears to be dependent on oxidative stress, as treatment with *n*-acetylcysteine, a potent antioxidant, is able to restore homeostatic cell-cycling conditions [84,85]. Activation of p38 mitogen-activated protein kinase (MAPK), a transcription factor, in response to ROS generation, is also important for regulating HSCs in the face of oxidative stress. MAPK activation limits the lifespan of progenitor cells, and inhibition of p38 pathways protects the self-renewal capabilities of HSCs, avoiding their exhaustion and thus being a potential therapeutic target for improving the "stemness" of HSCs [79,86].

These reports highlight the complexity of the processes responsible for regulating HSC physiology in hematopoiesis and how fragile this vital system is. Moreover, the maturation and differentiation of hematopoietic precursor cells leading to the delivery of mature cells into the bloodstream also involves fine-tuning mechanisms, which can be easily disrupted. Disturbances on HSC biology and functions and on the delivery of precursors into the bloodstream are mechanisms of blood and vascular diseases. The hematopoietic hierarchy alongside indications of HSC damage leading to senescence and apoptosis is summarized in Figure 1B.

## 2. Cellular and Molecular Mechanisms of Toxicity on Hematopoiesis

The amount of pollutants in the environment has increased in the modern era. Air pollution before industrialization mainly originated from the burning of organic materials used for house-heating and cooking. Such pollution resulted in increased releases of carbon monoxide and particulate matter, which by then already affected the health of populations [87]. Since industrialization, the amount and diversity of pollutants in the air have increased, and alarming levels of pollutants have been quantified in several countries worldwide, regardless of them being developing or having already been developed [88,89]. Consequently, hazardous effects for both the environment and human health have led to public health concerns worldwide. The complexity of hematopoiesis and of the fine-tuning mechanisms that control functions of blood components such as host defense, oxygen supply for tissues, and bloodstream rheology makes the hematopoietic system a suitable target for the actions of xenobiotics, including those released to the environment. Blood is also a pivotal matrix used for the assessment of xenobiotic levels and biological end points during intoxications. Below is described the most relevant data on the cellular and molecular actions of current environmental pollutants on the BM hematopoietic system in mammals.

## 2.1. Benzene and Its Metabolites

Benzene (BZ) is a volatile liquid aromatic hydrocarbon solvent, a byproduct of petroleum refinement. It used to be widely employed as an industrial chemical, either as a solvent or as a starting material for the synthesis of other chemicals, until its severe toxicity to occupationally exposed humans, especially by inducing hematological disorders and cancer, was described [90,91]. While the relationship between BZ exposure and leukemia had already been reported at the beginning of the 20th century in industry workers [91], BZ was classified as an environmental carcinogen in 1982 due to its BM toxicity [92]. Nowadays, even though the use of BZ in working environments is controlled around the world [93], alarming levels of this solvent are frequently found in the air of both developing and developed countries [94,95]. BZ, alongside toluene and xylene, is a contaminant of gasoline and diesel, thus being a common pollutant in high-traffic cities [96,97]. Smokers are also exposed to high amounts of BZ and its metabolite hydroquinone (HQ), which are compounds of cigarettes [98,99].

BZ is extensively metabolized after absorption via lungs, mouth, and skin, and the resulting metabolites are responsible for its harmful effects. BZ is initially converted to benzene oxide by cytochrome P450 enzymes, mainly CYP2E1, in the lungs and liver; benzene oxide is then rearranged into phenol, which is subsequently metabolized to HQ, catechol, and 1,4-benzoquinone (1,4-BQ) by action of CYP2E1 enzymes, especially in the liver. HQ is transported to the BM and metabolized to the highly reactive BQ by oxidative enzymes, such as myeloperoxidases (MPOs) [100]. Benzene oxide can also be hydrolyzed generating catechol and 1,2-BQ, or it can be metabolized by glutathione S-transferases forming the less-toxic metabolite *S*-phenylmercapturic acid. Benzene oxide can also have its aromatic ring opened, resulting in reactive muconaldehydes and *E,E*-muconic acid [100], which are quantified in urine as intoxication end-points. Detoxification by redox systems in BM, such as NADPH-quinone oxidoreductase 1 (NQO1), reduces the local levels of oxidative toxic agents generated by BZ metabolism [100,101], but prolonged exposure to BZ leads to lasting high levels of BZ and accumulation of BQ, which lead to toxic effects in BM. The role of redox systems on BZ toxicity has been evidenced by several reports as lower and higher hematotoxicity caused by BZ in CYP450 and NQO1 knockout mice, respectively [102,103]. NQO1 polymorphism is associated with increased hematotoxicity in humans exposed to BZ [104], and administration of the major compounds of garlic, diallyl di and trisulfide reduces BZ hematotoxicity in mice by deactivating CYP2E1 and MPO and activating GSH and NQO1 [105].

BZ exposure affects BM by interfering with different hematopoiesis pathways due to actions of its multiple metabolites, mainly HQ and BQ. This leads to failures in the BM environment, which result in decreased peripheral counts of erythrocytes, leukocytes, platelets, pancytopenia, aplastic anemia, myelodysplasia, and myelogenous leukemia [90,100,106,107]. Robust studies carried out over the years have evidenced that BZ exposure affects BM cells by causing chromosomal aberrations, gene mutations, oxidative stress, apoptosis, epigenetic deregulation, impairment of DNA repair, modification of protein secretion, and suppression of immune systems [90,91]. It is worth mentioning that toxic effects are not due to direct actions of BZ and its metabolites only, as these are also powerful inducers of ROS generation, and high ROS levels also mediate the harmful effects of BZ intoxication [90].

It is worrisome that there are no described safe levels for BZ exposure regarding hematopoiesis. BZ toxicity is influenced by different genetic profiles and living conditions; blood cell functions and their production and delivery processes are very intricate and offer a great number of targets for BZ metabolites to act upon [101,108]. Novel toxic mechanisms exerted upon hematological parameters by BZ exposure have been continuously reported, especially for exposures at levels considered sub-toxic [108,109].

As the overall population should not be exposed to high levels of BZ, elucidating how BZ exposures of low frequency and low doses disturb cell pathways is a goal of current investigations. Indeed, gene alterations in human HSCs have been fully demonstrated after low-dose exposures to BZ (lesser than 1 ppm, the threshold level), resulting in aberrant expression of downstream genes, malignant transformations, and HSC dysfunction [110–112]. Exposure of HSCs to non-cytotoxic doses

of BZ have caused ruptures of DNA structures at breakpoint hot spots in the leukemia-related genes MLL and CBFβ similar to those found in leukemia patients [113]. DNA breaking within the MLL gene leads to rearrangement of over 120 other partner genes, resulting in acute leukemia with poor prognostics [114], and DNA breakings within the CBFβ gene is the cause for about 10% of acute myeloid leukemia cases [115]. Enhanced autophagy is another mechanism elicited by lower levels of BZ exposure, as reported in BM mononuclear cells from patients exposed to BZ and in mice cells exposed to HQ. Autophagy is regulated by post-translational modifications such as phosphorylation, ubiquitination, and acetylation. BZ exposure reportedly decreases acetylation of autophagy components by inhibiting the activity of acetyltransferases such as p300 [116]. Hematopoietic cells collected from workers exposed to low doses of BZ or incubated with 1,4 BZ have shows increased apoptosis and autophagy rates, dependent on expression of the long-non-coding RNA cRNAVNN3 triggered by BZ or 1,4 BZ-induced oxidative stress; cRNAVNN3-enhanced phosphorylation of Bcl-2 and beclin-1 led to cell death [117]. Physiological autophagy levels are required for maintaining stable cell homeostasis under stress conditions, while exacerbated autophagy induces uncontrolled cell death. Therefore, depending on the intensity of the aggressive stimuli, autophagy can be either beneficial or harmful, playing either a protective role on cell death or contributing to it [118].

HIF-1 $\alpha$  is a transcription factor involved in the harmful effects of BZ on HSC niches. HIF-1 $\alpha$  controls the hypoxic microenvironment of such niches as to maintain quiescence, survival, and metabolic phenotypes of cells by increasing anaerobic glycolysis and reducing ROS generation [78,82,119]. Recent evidence has demonstrated that exposure to BZ can inhibit HIF-1 $\alpha$ , as mice exposed to BZ showed high levels of ROS alongside lower levels of HIF-1 $\alpha$  in niches of stem cells [120]. HIF-1 $\alpha$  binds to DNA in the hypoxia-response-element (HRE) DNA domain, and several genes such as those responsible for the expression of vascular endothelial growth factor (VEGF) and erythropoietin (among others) contain HRE binding sites in their sequences and are thus targets for the actions of HIF-1 $\alpha$ . It has been demonstrated that treatment of BM cells from mice with BZ downregulated expression of genes containing the HRE domain, impairing expression of genes involved with self-renewal, cell cycle, differentiation, and apoptosis pathways of HSCs [121]. In accordance, overexpression of HIF-1 $\alpha$  in a myelogenous leukemia (CML) K562 cell line reduced apoptosis and ROS levels induced by 1,4-BQ by targeting Nox4, Bcl-2, and key glycolytic enzymes [122].

Reduction of the number of circulating red blood cells is also a clinical symptom of low intensity BZ toxicity [123]. It has been demonstrated that damage caused to erythroid burst-forming units (BFU-E) in workers exposed to BZ is dose-dependent, and that erythroid cell differentiation is more sensitive to the harmful effects of BZ or HQ exposure than other hematopoietic precursor cells [124,125]. It has also recently been reported that BZ inhibited erythroid cell differentiation by downregulating the expression of miRNA-451a and miRNA486-5p [126]; miRNA-451a positively modulates the terminal differentiation of erythroid cells protecting red cells against oxidative stress [127,128] and miRNA486-5p regulates the differentiation and growth of erythroid cells [129].

Another topic of BZ toxicity that is yet to be fully elucidated is whether hematopoiesis disturbances caused by BZ exposures of low frequency and dose are reverted after exposure ceases. It has been demonstrated that exposure to BZ in mice impaired frequency and colony formation of HSC SCA-1<sup>+</sup>c-kit<sup>+</sup> cells (LSK) and reduced mRNA levels of Notch-1 and p53 in BM cells collected 10 months after the end of BZ exposure. This provides evidence that molecular and cellular alterations affecting the self-renewal of HSCs are long-lasting after exposure to BZ, and may allow pre-leukemic clones to evade elimination, leading to an increased risk of development of transforming neoplasia [130]. In the same vein, exposure of rats to BZ at low doses for 14 days impaired erythropoiesis, which partially recovered 56 days after exposure has ceased as reduced numbers of reticulocytes in the bloodstream and reduced phagocytosis ability in macrophages collected from mature erythroblastic islands could be observed after this period [131].

The modulation of the cytosolic transcription factor aryl hydrocarbon receptor (AhR) linked to BZ toxicity on BM and blood cells has recently been investigated. AhR is a ligand-activated transcription

factor expressed in hematopoietic progenitor cells, lymphocytes, neutrophils, and splenocytes [132–134]. The connection between BZ exposure and AhR was first demonstrated by studies that provided evidence that hematopoietic toxicity induced by BZ was not observed in AhR knockout mice, but that toxicity would take place when the BM of animals was repopulated with cells from wild-type mice. Accordingly, BZ-induced hematotoxicity in irradiated wild-type mice repopulated with AhR knockout BM cells was not observed, as measured by granulocyte-macrophage-colony-forming units assay [135–137].

AhR expression is also essential for the differentiation and activation of Th17 cells in the pathogenesis of rheumatoid arthritis [138,139]. Solid experimental and clinical data show a correlation between exposure to cigarette smoking and the induction and aggravation of rheumatoid arthritis [140,141]; there is also increased AhR expression in the synovial membrane of smokers [142]. Cigarette smoke is an important source of BZ and HQ, as each stick delivers about 72.2 and 100 µg of BZ and HQ, respectively [99,143]. The connection between HQ exposure and AhR to rheumatoid arthritis was recently tested in mice and rats exposed to HQ by inhalation following an experimental design of low-dose exposures. Although HQ-exposed animals had no alterations in BM or blood cell numbers, disease symptoms worsened, with a high frequency of AhR<sup>+</sup> neutrophils and Th17 lymphocytes in the inflamed synovia. Accordingly, rheumatoid arthritis symptoms were not observed in AhR knockout mice exposed to HQ [133,134] (Heluany et al., under review). These data evidence that exposure to BZ metabolites worsens rheumatoid arthritis involving HQ actions through AhR on blood cells, and that both BZ and HQ are cigarette compounds involved with the harmful effects on the evolution of the disease as a result of cigarette smoking.

Although scientific studies regarding hematotoxicity evoked by BZ exposure have been published extensively in scientific literature over the last 50 years, the broad actions of BZ and its metabolites upon the complex hematopoietic phenomena and resulting effects to the immune system in exposed subjects, especially those exposed to low concentrations, constitute a still-vast area for investigations with a meaningful impact on public health.

## 2.2. Engineered Nanoparticles

Nanotechnology as a field has grown at a fast pace over the last 20 years, and has been responsible for the development of materials with useful properties for a plethora of industrial and biological applications in the engineering, communication, food, and textile industries, to name a few. Nanomaterials also have bioenvironmental applications, and can act as reliable drug carriers [144]. Nanoparticles (NPs) are sized less than 100 nm, and are characterized by an increased surface area and unique physicochemical properties, which make them extensively employed in several fields. Due to NPs being such a recent breakthrough, the number of studies focusing on subjects occupationally exposed to NPs is still low, but increasing. The impact of NPs on occupational health and safety is currently difficult to predict, halting advances on the risk assessment of NPs [145]. The main factors that determine the toxicological effects of NPs are exposure conditions such as route, concentration, and duration; the individual characteristics of exposed subjects; and the intrinsic characteristics of NPs, including ability to bind to or coat surface species, surface area, composition, and catalytic activity, among others [146]. Moreover, NP pharmacokinetics differ from those of common bulk materials, which is another barrier to advances on understanding their toxicological potential [147].

Current nanomaterial research has mostly focused on nanotechnology applications, whereas there is little information regarding occupational and environmental exposure assessment and risk characterization associated with NPs. As airborne NPs are mainly absorbed by respiratory routes, some of the toxic effects of NPs on lungs have been described in both humans and experimental animals, being characterized mostly by inducible inflammatory reactions [144]. Still, inhaled NPs have a very small size and can be arrested from alveoli into other tissues by the bloodstream, which may lead to systemic harmful effects [148]. Indeed, it has been demonstrated that pulmonary instillation of titanium dioxide (TiO<sub>2</sub>) NPs has resulted in increased plaque deposits in atherosclerosis-prone apolipoprotein E-deficient mice [149]. In addition, environmental exposure to TiO<sub>2</sub> NPs has affected

the biology of circulating angiogenic cells (EPCs), which contribute to the harmful vascular effects of NPs [150]. After birth, EPCs circulate in the peripheral blood until being recruited and incorporated into sites of active neovascularization, being then committed to vascular repair [37,151].

No clear evidence is available regarding the effects of occupational or environmental exposure to NPs on hematopoiesis in BM. Nevertheless, alterations in the number and functions of circulating immune cells have been described in addition to those induced by the inflammatory response by itself as a result of exposure to NPs. Magnetic NPs have been extensively used as contrasting agents in magnetic resonance imaging; assessment of toxic effects due to the inhalation of manufactured magnetic NPs has revealed these NPs to be highly distributed to different tissues and to increase hematopoiesis in the spleen, where there are increased numbers of erythroid and myeloid cells in the red pulp [152].

Although studies available on the harmful effects of engineered nanotechnology products on the hematopoietic system are scarce, the systemic toxic effects of NPs that unintentionally reach complex tissues (such as the central nervous system [153]) have shown evidence that further investigations on the toxic potential of NPs on BM could provide valuable data for risk assessment studies.

### 2.3. Incidental Environmental Nanoparticles and Particulate Matter

Exposure to NPs or particulate matter (PM) found in polluted air causes systemic harmful effects, which have been extensively described in humans, and exposure to associations of NPs and PM can lead to the onset of diseases as well [154–156]. PM comprises a heterogeneous mixture of particles of different sizes and chemical compositions. The severity of toxic systemic effects is closely linked to particle size, as both NPs and PM 2.5 (smaller than 2.5  $\mu\text{m}$ ) can reach the bloodstream from alveoli and be distributed into tissues causing systemic effects [157–160]. Particles can also contain harmful airborne microorganisms and metals, which greatly increase their toxicity [161,162]. The World Health Organization estimates 92% of the global population lives in areas where the levels of fine PM 2.5 exceed the recommended annual average air concentration limit of 10  $\mu\text{g}/\text{m}^3$ . Recent findings have shown that exposure to PM 2.5 can pose hazards to public health at low levels, even below those recommended by regulatory agencies [154,163–167].

Local and systemic inflammation, especially linked to chronic exposures, is a common hallmark of exposure to airborne NPs and MPs [160,168]. Cytokines secreted at inflammation sites reach BM and alter HSC niches, affecting maturation and differentiation phases of leukocytes and delivery of cells into the bloodstream. Both acute and chronic *in vivo* exposure to PM are reported to cause lung inflammation and leukocytosis due to an increased release of immature granulocytes into circulation [169]. This effect was evidenced by increased numbers of band neutrophils found in the bloodstream and a reduced monocyte transit time in BM after lung instillation of PM 10 in rabbits; this effect was also observed in rabbits instilled with supernatant culture medium of alveolar macrophages incubated with PM 10, but not in rabbits instilled with supernatant collected from alveolar macrophages incubated with inert carbon [169,170]. Thus, PM 10 actions depend on activation of lung macrophages, followed by secreted chemical mediators reaching BM and inducing neutrophil and monocyte delivery into the bloodstream [171,172].

The association between PM 2.5 exposure and cardiovascular morbidity and mortality has been extensively demonstrated in epidemiological and experimental studies [173,174]. Both direct and indirect actions of these particles on BM have been shown. Toxic effects on the cardiovascular system caused by MP 2.5 are characterized by alterations on blood rheology and endothelial cells of blood vessels, mostly associated with endothelial oxidative stress and inflammation [175,176]. Moreover, it a tracheal instillation of PM 2.5 from diesel exhaust in mice was reported to have increased the mobilization of neutrophils from BM, and the resulting neutrophilia led to myocardial oxidative stress [177]. Solid evidence has demonstrated that *in vivo* exposure to PM 2.5 affects BM by limiting the inherent functionality and mobilization of EPCs into the bloodstream, as acute exposure of humans or mice to PM 2.5 has been negatively correlated with plasma levels of EPCs [178,179]. In addition,

EPCs from the BM of mice exposed to PM 2.5 have displayed reduced proliferation and tube formation capabilities that were not due to cell death, but rather dependent on the downregulation of genes that support cell proliferation and the cell cycle of BM EPCs. These effects were absent in overexpressing extracellular superoxide dismutase eSOD-Tg mice exposed to PM 2.5, resulting in reduced oxidative stress and higher nitric oxide bioavailability even upon exposure to PM 2.5. GSH levels were also reduced in BM cells obtained from PM 2.5 exposed mice [179]. Therefore, harmful effects on BM EPCs caused by exposure to PM 2.5 may comprise likely mechanisms for its toxic effects linked to cardiovascular morbidity and mortality.

Other studies further evidenced the toxic effects of PM on BM cells, as incubation of PM 2.5 or PM 10 collected from polluted air impaired proliferation of human HSCs in a concentration-dependent manner, increased expression of cytokine genes associated with inflammation (e.g., TNF- $\alpha$  and IL-6), and impaired expression of the cell cycle regulator gene p53 [180].

Recent studies have described associations between exposure to PM 2.5 during pregnancy and effects on HSCs in the BM of offspring. Pups from female mice exposed to PM 2.5 via respiration during pregnancy suffered from lung inflammation and oxidative stress, which lasted until adulthood. Although offspring aged two and six months had normal leucograms, the two-months-old offspring showed increased BM oxidative stress, inflammation, and osteoclast activity. Damage done to BM evolved and six-months-old offspring exhibited senescent phenotypes of BM HSCs, demonstrated by reduced clonogenic formation, donor-cell-derived reconstitution and self-renewal, increased levels of mitochondrial ROSs, NrF2 expression, cyclin-dependent kinase inhibitors, and increased p38 phosphorylation and DNA double-strand breaking. Considering that no effects were observed on the BM of exposed dams, it is likely that offspring from mothers exposed to PM 2.5 have less efficient anti-oxidant mechanisms in their BM than their mothers [181].

Although scientific studies assessing exposure to PM and BM effects are not plentiful, this only reifies that the BM microenvironment should be considered for risk assessment studies. BM is a direct target for the actions of PM, especially PM 2.5, enduring impairments on cell proliferation, lifespan, and functionality due to systemic oxidative stress and inflammation.

#### 2.4. Dioxins and Polychlorinated Biphenyls (PCBs)

Dioxins are persistent organic pollutants (POPs) released to the atmosphere as undesired byproducts of an anthropogenic and natural origin. These compounds can originate as byproducts from combustion processes, such as the incineration of solid waste, the chlorine bleaching of paper and wood-pulp, the burning of coal in power plants, and forest wildfires [182]. These pollutants also occur as contaminants in several pesticides, herbicides, and fungicides [183]. Among POPs, dioxins are considered the most hazardous to human health, with their major toxic effects being linked to binding to the aryl hydrocarbon receptor (AhR) in several cell types.

PCBs make up a class of 209 volatile, structurally related organochlorine compounds used for different industrial and commercial applications, which were mass-produced until the 1970s. Since then, PCBs have been identified as carcinogens, and their global commercial production was banned by signatory nations in the Stockholm Convention on Persistent Organic Pollutants in 2001 [184,185]. Nevertheless, PCBs continue to pose a significant risk to human health through exposure sources such as the continuous release from hazardous waste sites, PCB-contaminated equipment that is still in use, and contact with construction materials used in buildings erected prior to the PCB production ban. In addition, non-legacy PCB congeners have also been detected in paint and industrial pigments [186]. PCBs are still considered among the most important groups of food contaminants, and food and agricultural authorities strictly monitor the PCB contamination of foods. As air pollutants and contaminants of extensively used organochlorine pesticides, PCBs contaminate foods in the same manner as described above, by being byproducts of industrial processes, the combustion of certain materials, or accidental fires. Recycling and the production of certain minerals can also produce PCBs [187]. Depending on the position of chlorine atoms in the biphenyl backbone, PCBs can be

of planar or non-planar geometry. Non-chlorine substitution in the ortho position determines non co-planar geometry, while substitution of one to four chlorine molecules in the ortho position determines varying degrees of co-planar ring geometry. Co-planar congeners bind to AhR and are therefore called dioxin-like PCBs. Among 209 known PCB congeners, 12 can bind to AhR [188]. Long degradation half-life and high liposolubility contribute to the bioaccumulation of dioxin and PCBs in biological organisms [189].

AhR is a cytoplasmic basic helix-loop-helix/PAS transcription factor that, upon activation by ligands, can lead to either physiological or toxic effects. AhR has traditionally been described as a central regulator of responses to environmental factors and of xenobiotic metabolism. First studies on the toxic effects of dioxins and AhR evidenced 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD, dioxin) can bind to AhR, leading to several toxic effects [190,191]. Under homeostatic conditions, AhR remains predominantly in the cytoplasm as part of a protein complex linked to molecular chaperone heat shock protein 90 (HSP90), p23, and XAP2 [192]. Several stressors can drive AhR activation and evoke its conformational transition, resulting in its nuclear translocation [193]. AhR then dissociates from HSP90 and binds to the AhR nuclear translocator (ARNT), and the AhR/ARNT complex binds to promoter regions in the DNA known as AhR-responsive DNA elements or xenobiotic response elements (XREs), which leads to an increased expression of target genes (e.g., cytochrome P450 (CYP) 1A1, CYP1A2 and CYP1B1) [193,194]. This canonical pathway for AhR activation mediates several toxic responses, including liver damage, chloracne, teratogenesis, cancer, and immunosuppression [195,196].

In recent years, research has demonstrated that AhR-null mice suffer from developmental impairments, evidencing AhR as a crucial homeostasis modulator in several tissues and biological processes, including hematopoiesis [197,198]. AhR modulation on HSC self-renewal, proliferation, cell cycle, and senescence has been demonstrated by the *in vivo* gene deletion of the AhR exon 3. HSCs from AhR knockout mice abandon quiescence and become hyperproliferative, revealing that AhR is likely a negative regulator of excessive or unnecessary proliferation [197–199]. AhR also affects the maturation of HSCs by acting on progenitor strains. AhR deletion in human embryonic stem cells, or blocking of these cells with AhR antagonists, leads to increased differentiation into CD34<sup>+</sup>, CD45<sup>+</sup>, and CD31<sup>+</sup> EPCs [200,201]. Conversely, in later maturation phases, AhR deletion favors the proliferation of myeloid colonies [201].

Epidemiologic studies have demonstrated associations between 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), the most toxic member of the polychlorinated dibenzodioxins (PCDD) family, and onco-hematologic diseases, particularly non-Hodgkin lymphomas, chronic lymphocytic leukemia, and multiple myeloma [202–204]. Indeed, the BM of adult mice exposed to acute doses of TCDD becomes hypocellular, with a significant decrease in the total number of HSCs—effects that are not due to cell death, but rather to direct AhR modulation [205].

Exposure to TCDD impairs humoral responses, and it has been determined that such exposure can lead to B-cell disorders and increased incidence of B-cell-derived cancers [206,207]. Mice exposed to TCDD have shown a reduced number of B-cell progenitors [208] and skewed HSC differentiation favoring myeloid progenitors to the detriment of lymphoid progenitors, giving rise to mature B cells [110,209]. It has also been reported that HSCs treated with TCDD are not able to repopulate the BM of irradiated mice [210,211]. Gene analysis of HSCs revealed that TCDD treatment modified the transcription of genes linked to both migration—such as CD184 (CXCR4) and CD44—and the development and function of the hematological system (e.g., Fos, JunB, Egr1, Ptgs2, and CXCL2) [212].

TCDD is not only toxic to HSC, and its effects on BM stromal cells can also contribute to decreased B-cell numbers. Exposure to TCDD downregulates IL-6 gene transcription in stromal cells, inhibiting the growth of early B-cell progenitors in a NF- $\kappa$ B-dependent manner [213]. Inefficient humoral responses in offspring from mothers exposed to TCDD and dioxin-like PCBs has led to the reprogramming of hematopoietic stem and progenitor cells during development [214].

The toxic effects of dioxins upon the hematological system demonstrate the importance of AhR on the control of proliferation, function, and migration of hematological progenitor cells in BM.

Even though dioxin-like xenobiotics are capable of strongly binding to AhR, and of causing severe toxic effects in humans, the harmful effects caused to the hematological system, mainly impairing humoral responses, are suitable end points for the risk assessment of dioxin exposure.

## 2.5. Heavy Metals

The number of individuals exposed to heavy metals increased throughout history in accordance with industrial and urban growth, eventually leading to researchers investigating correlations between exposure to metals and the onset of diseases [215]. Heavy metals (HMs) are raw materials of great importance for the steel cutting, welding, electroplating, plastics, and automobile industries [216]. HMs are classified by their atomic number, atomic weight, density, and toxicity, of which chromium (Cr), lead (Pb), mercury (Hg), cadmium (Cd), arsenic (As), copper (Cu), manganese (Mn), nickel (Ni), zinc (Zn), and silver (Ag) are the most relevant for human exposure and toxicity [217]. Among these HMs, Pb, Cd, As, and Hg have been described as harmful to BM, causing anemia and immune deficiencies, as evidenced by epidemiological and clinical studies and by experimental models of intoxications caused by these HMs.

Levels of HM in the atmosphere, in the occupational environment, and in biological samples can all be used to measure the impact of HM exposure on the health of workers and of the general populations residing in industrial areas [215]. Acute exposure to HMs can severely damage lungs, liver, kidneys, and the central nervous system (ATSDR, 2004). Long-term exposure can lead to HM bioaccumulation not only in humans, but also in crops, soil, and wildlife used as food sources, indirectly affecting humans [218,219]. While acute exposures to HMs knowingly causes severe toxic effects, concerns by public health authorities are currently focused on chronic, low-dose exposures, which can lead to cumulative effects. Even exposures to HMs at levels lower than those assigned for “safe” threshold values are potentially toxic, resulting in cancer, neurological damage, and infertility, among other effects [220–222].

Exposure to HMs can cause disturbances in the hematological system and can be used as biological end-points for assessing HM exposure; HM intoxications cause immunosuppression, anemias, and leukemias and disrupt coagulation [223–226]. While HM exposure can directly impact circulating blood cells, several toxic effects occur in the BM environment and affect hematopoiesis.

### 2.5.1. Lead (Pb)

Exposure to Pb reduces the number of blood cells, including both erythrocytes and leukocytes. Toxic effects on BM due to Pb exposure have been described even at lower levels in humans under occupational exposures or in animal experimental intoxication models [227]. In this context, mice exposed to Pb have displayed reduced numbers of colony-forming units in their BM [228], and exposure to Pb impaired differentiation of CMPs, resulting in decreased numbers of mature myeloid cells [229]. Mechanisms associated with these effects involve higher expressions of interferon regulatory factor-8 (IRF8), which blocks C/EBP $\alpha$  and modulates neutrophil differentiation [230]. Recent evidence shows that exposure to Pb at occupational levels can result in lower numbers of innate lymphoid cells (ILCs) in the blood of mice, with this effect being dependent on activation of Janus Kinase-1 leading to an inability of BM CLP progenitors to become mature and be delivered into the bloodstream [231]. CLPs differentiate into innate lymphoid cell-restricted progenitors via transcription factor ID2, which further differentiate into mature ILC 1, 2, and 3 [232]. Under stimulation, mature ILC 1, 2, and 3 are activated and exert functions similar to those exerted by Th1, Th2, and Th17 cells, respectively [233,234]. These functions play roles during the innate immune response occurring in certain scenarios, such as during asthma, tumors, and tissue remodeling [235,236], all of which are aggravated due to Pb exposure.

Pb intoxication also interferes with erythropoiesis, as evidenced by aplastic anemia. High levels of reactive oxygen species seem to be the mediators of this effect, as children with aplastic anemia are reported to show higher levels of Pb in the blood alongside increased markers of oxidative stress [237].

### 2.5.2. Cadmium (Cd)

Humans are exposed to Cd derived from occupational activities, cigarette smoking, Cd-contaminated dust and ingestion of contaminated food [238]. Cd is extensively distributed to other tissues and has a long half-life (approximately 10 years), contributing to its high toxicity [239]. Much like Pb exposure, Cd exposure affects the differentiation and functionality of HSCs in BM. It has been reported that mice exposed to Cd showed increased myelopoiesis to the detriment of lymphopoiesis, there being higher numbers of neutrophils and lower numbers of B and T lymphocytes in the bloodstream and in secondary lymphoid tissues. Cd exposure is also harmful to HSC niches in BM, as transplantation of normal HSCs to Cd-exposed and lethally irradiated mice did not repopulate the BM, whereas HSCs from Cd-exposed mice partially reconstituted the hematopoietic system of non-exposed and lethally irradiated mice [240]. A recent study carried out in mice further demonstrated that Cd exposure impaired the HSC ability to repopulate the BM of lethally irradiated recipients, and this toxic effect upon HSCs is dependent on increased expression of *cdc42*, a small GTPase crucial for HSC functions in mice. Indeed, pharmacological blocking of *cdc42* restored the hematopoietic ability of HSCs from Cd-exposed mice [241].

### 2.5.3. Arsenic (As)

As is considered to be among the metals most capable of causing harmful effects to human health. Geologically distributed in pentavalent ( $As^{5+}$ , arsenate) and trivalent ( $As^{3+}$ , arsenite) forms in some regions of the world, its concentration in soil and water exceeds in up to 10 times allowed levels, according to the World Health Organization [242]. The most common form of contact with As is through contaminated water consumed either directly or through food. Absorption via inhalation also occurs during the handling of pesticides, fungicides and paints. Arsenic metabolism determines its toxicity, as trivalent arsenic, either methylated or not, easily reacts with thiol groups in proteins and is thus more toxic than pentavalent arsenicals [243].

Studies using murine models have found that exposure to arsenic in drinking water can result in anemia and impaired immune responses elicited by mononuclear cells [244–248]. These effects have also been confirmed in humans [249]. As can be easily distributed to several tissues through the bloodstream, reaching BM where it causes toxic effects. Indeed, arsenic trioxide ( $As_2O_3$ ) administered to mice severely damages the BM microenvironment, making stromal cells unable to form a healthy matrix to support hematopoietic progenitors [250].

Epidemiological studies carried out in Bangladesh and Romania, areas characterized by geogenic contamination of underground drinking water, correlated chronic As exposure with anemia [251–254]. A case report demonstrated pronounced histological alterations in the BM of a patient suffering from arsenic poisoning, characterized by marked nuclear aberrations involving nucleus shape, chromatin distribution, and nuclear envelope [255]. In vitro analyses showed that the molecular mechanism for toxicity of arsenic trioxide in erythroleukemic cell lines and on normal hemopoietic progenitor cells (HPCs) involves several pathways, such as inhibition of Stat5 activation and reduced expression of target genes *Bcl-X(L)* and *glycophorin-A*; activation of apoptotic mechanisms leading to cleaving of erythroid transcription factors *Tal-1* and *GATA-1*, whose integrity is required for erythroid cell survival and differentiation; and reduced expression of heat shock protein 70, which is required for maintaining *GATA-1* integrity [256]. In vivo, exposure to arsenite also impaired the formation of burst-forming unit-erythroid (BFU-E) colonies and the differentiation of erythroblasts into further stages in mice [257].

### 2.5.4. Mercury (Hg)

Mercury intoxications usually occur due to acute exposures to its natural form during extraction of fossil fuels, burning of biomass, forest fires, and deforestation [258]. However, exposure to small concentrations, which occurs during contact with dental amalgams, consumption of fish and other

seafood from contaminated regions, and occupational exposure (e.g., farming, industrial activities, and gold mining), can also affect human health [259]. Hg is toxic to virtually every human organ; due to its affinity for sulfhydryl groups, Hg alters tertiary and quaternary structures of proteins and disrupts membrane permeability [259]. Disturbance of hematopoietic systems is also a hallmark of Hg intoxication, characterized mainly by anemia and lymphocytopenia [223,260].

The harmful effects of Hg on BM were first demonstrated in patients with BM hypoplasia [261]. Exposure of mice BM cells to inorganic and organic Hg inhibited colony formation [262], and exposure to Hg in rat BM cells inhibited activities of acetylcholinesterase, glutathione reductase, and glucose-6-phosphate [263,264]. Even though absorbed Hg reaches BM (Dabrowski et al., 1983), *in vivo* toxicity seems to be dependent on higher exposure doses and on frequent exposures, as low dose exposures caused only minor and transient impairments on lymphocyte production in mice [265,266]. Recently, toxic mechanisms associated with long lasting exposure to Hg in mice have been linked to a decreased proliferation of HSC, which is dependent on reduced levels of interferon gamma in BM [225].

Intoxications caused by HM, especially Pb, Cd, As, and Hg, have severe harmful effects on the hematopoietic systems, leading to anemia and immune deficiencies, and it is intriguing that mechanisms linked to such toxic effects have not yet been more thoroughly assessed. These metals reach BM and easily interact with proteins, affecting several hematopoietic pathways. Further studies on cellular and molecular mechanisms linked to the toxic actions of metals in BM should investigate additional toxic effects arising from such interactions.

### 3. Conclusions

Exposure of living beings to environmental pollutants has increased, influencing public health policy-making even in scenarios where exposures are below thresholds considered safe. Simultaneous exposure to different air pollutants also certainly contributes to the increase of alarming data, which has been evidenced in epidemiological studies. Hematopoiesis is pivotal for hemostasis and host defense, and disturbances on this process lead to severe outcomes, as summarized in Figure 2. Advances in scientific knowledge regarding hematopoiesis mechanisms have evidenced novel targets for actions of xenobiotics not yet described, hence further studies on hematopoiesis are needed for improving environmental pollutant risk assessment.

**Figure 2.** Molecular and cellular mechanisms linked to toxic effects of environmental pollutants on hematopoiesis. (A) Benzene (BZ) is metabolized by CYP2E1 in liver and lung generating hydroquinone (HQ) and catechol (Cat), which are then transformed into benzoquinone (BQ). These metabolites exert myelotoxic actions upon several hematopoietic progenitors mainly by increasing levels of reactive oxygen species (ROSs), leading to oxidative DNA damage. (B) Nanoparticles and particulate matter induce generation of ROSs and secretion of inflammatory cytokines that affect the behavior of several hematopoietic cell lineages. (C) Dioxins and PCBs bind to and activate the aryl hydrocarbon receptor (AhR) in mucosal tissues, modulating the hematopoietic stem cell (HSC) pool and triggering both immunosuppressive effects and myelodysplastic and malignant abnormalities. (D) Heavy metals can enter the body via several contact routes, their toxic effects being responsible for impairing inflammatory responses and triggering leukemias and anemias.

**Funding:** The authors thank the Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP; research grants nr. 2014/07328-4, approval date 30 November 2014 and 2019/19573-7, approval date 20 May 2020) for providing funding support to MFB (2018/26383-7, approval date 1 April 2019) and GHOR (2017/05430-4, approval date 1 October 2017) and also thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for providing funding support to PS (130090/2019-0, approval date 16 January 2019).

Ulcerative colitis and Crohn's disease are chronic inflammatory bowel diseases (IBDs) which burden health systems worldwide; available pharmacological therapies are limited and cost-intensive. Use of peroxisome proliferator activated-receptor  $\gamma$  (PPAR $\gamma$ ) ligands for IBD treatment, while promising, lacks solid evidences to ensure its efficacy. Annexin A1 (AnxA1), a glucocorticoid-modulated anti-inflammatory protein, plays a key role on IBD control and is a potential biomarker of IBD progression. We here investigated whether effects of pioglitazone, a PPAR $\gamma$  ligand, rely on AnxA1 actions to modulate IBD inflammation. Experimental colitis was evoked by 2% dextran sodium sulfate (DSS) in AnxA1 knockout (AnxA1 $^{-/-}$ ) or wild type (WT) C57BL/6 mice. Clinical and histological parameters were more severe for AnxA1 $^{-/-}$  than WT mice, and 10mg/kg pioglitazone treatment attenuated disease parameters in WT mice only. AnxA1 expression was increased in tissue sections of diseased WT mice, correlating positively with presence of CD68 $^{+}$  macrophages. Metalloproteinase-9 (MMP-9) and inactive 33kDa AnxA1 levels were increased in the colon of diseased WT mice, which were reduced by pioglitazone treatment. Cytokine secretion, reactive oxygen species generation and MMP-9 expression caused by lipopolysaccharide (LPS) treatment in AnxA1-expressing RAW 264.7 macrophages were reduced by pioglitazone treatment, effects not detected in AnxA1 knockdown macrophages. LPS-mediated increase of AnxA1 cleaving in RAW 264.7 macrophages was also attenuated by pioglitazone treatment. Finally, pioglitazone treatment increased extracellular signal-regulated kinase (ERK) phosphorylation in AnxA1-expressing RAW 264.7 macrophages, but not in AnxA1-knockdown macrophages. Thus, our data highlight AnxA1 as a crucial factor for the therapeutic actions of pioglitazone on IBDs.

**Keywords:** inflammatory bowel disease, experimental colitis, pioglitazone, macrophage, annexin A1

## INTRODUCTION

Ulcerative colitis and Crohn's disease comprise inflammatory bowel diseases (IBDs), which are widespread and pose burdens to healthcare systems worldwide (Mak et al., 2020). In 2016 in the United States alone, the prevalence of both maladies combined was last reported to be of one for every 209 people, and incidence increases steadily each year (Luther and Dave, 2020); also, the estimated loss of earnings due to IBDs were calculated as \$31 billion in the same year (Xu et al., 2018). Patients suffer from diarrhea, anemia, fatigue and severe gut pain, among other symptoms, which become more intense during acute episodes, causing them to lose workdays and drastically reducing quality of life (Xu et al., 2018). Pharmacological options to treat these diseases are limited, as traditionally used drugs address only the major symptoms of inflammatory bowel diseases and fail to conduct patients to complete remission (Duijvestein et al., 2018). Biological therapies involving anti-TNF $\alpha$  antibodies, such as infliximab, while proven successful and better than conventional drugs, do not cause any response in about a third of patients and are very cost-intensive (Hossain et al., 2020). There is also a trend nowadays for new IBD therapies to aim for objective targets in an individualized manner rather than following pre-determined therapy paradigms (e.g., aim for mucosal healing rather than "overall remission"), and thus the understanding of new IBD biomarkers and of how new or already existing drugs work and with which other molecules they interact on intestinal tissue becomes a necessity (Im et al., 2018; Ho et al., 2020).

Annexin A1 (AnxA1), a 37 kDa protein modulated by the actions of glucocorticoids is one such molecule currently assessed as a potential target for therapy of not only IBDs, but of other inflammatory chronic diseases as well, playing roles on the inflammatory modulation of diseases such as asthma, type-2 diabetes, cystic fibrosis, rheumatoid arthritis, among others (Patel et al., 2012; Perretti and D'acquistio, 2009; Perucci et al., 2017; Sheikh and Solito, 2018). It is expressed by epithelial cells and monocytes, neutrophils and macrophages to a great extent (Perretti and D'acquistio, 2009). In IBD animal models, AnxA1 and its N-terminal mimetic peptides are known to attenuate disease progression and promote epithelial repair (Babbin et al., 2008; Ouyang et al., 2012; Zou et al., 2016), and when lacking halts disease remission caused by treatment with infliximab (de Paula-Silva et al., 2016). AnxA1 expression is increased in intestinal tissue of ulcerative colitis patients while decreased in Crohn's disease patients, evidencing these diseases deregulate AnxA1 actions leading to compromised anti-inflammatory responses (Vong et al., 2012; Sena et al., 2013). It has been reported AnxA1 also plays a role on healing of damaged intestinal epithelium on murine IBD models, and that its expression is correlated with better prognosis on Crohn's disease patients (Leoni et al., 2015; Reischl et al., 2020).

While seemingly a beneficial role player on downmodulating inflammation, AnxA1 can be cleaved into smaller 33 kDa fragments which are believed to be non-functional and even lead to pro-inflammatory effects, such as increased neutrophil

transmigration via endothelium (Williams et al., 2010; Sugimoto et al., 2016); while this event has not yet been described in neither IBD patients nor in experimental colitis animal models, it has been evidenced cleaved AnxA1 correlates with increased inflammatory damage in animal pleurisy models and in neutrophils recruited from animals treated with LPS (Vago et al., 2012; Vago et al., 2016).

In the search for new pharmacological targets to treat IBDs, in the same vein as AnxA1, peroxisome proliferator activated  $\gamma$  (PPAR $\gamma$ ) has been explored as a potential transcription factor linked to modulation of IBD, and it has been evidenced its impaired expression is linked to disease progression in humans (Yamamoto-Furusho et al., 2011; Dou et al., 2015). PPAR $\gamma$  ligands such as thiazolidinediones have emerged as potential new anti-inflammatory candidates for IBD therapy, and first reviews on the efficacy of PPAR $\gamma$  ligands for treatment of IBDs date back 20 years ago (Wada et al., 2001). While traditionally used for treatment of diabetes, such ligands have been explored as anti-inflammatories in the past few years and shown as promising treatment options for several chronic inflammatory diseases, especially those that affect the central nervous system, such as Alzheimer's disease, Parkinson's disease and multiple sclerosis (Galimberti and Scarpini, 2017; Bonato et al., 2018). Pioglitazone, one such PPAR $\gamma$  ligand, is also effective in attenuating inflammation in alcoholic-induced cirrhosis livers and reducing specific histologic lesions in cancerous lungs of smokers (Chongmelaxme et al., 2019; Keith et al., 2019). On macrophages, pioglitazone is reported to induce M2 polarization, attenuate TNF $\alpha$  and IL-1 $\beta$  expressions, reduce actions of CXCL1 and CCL2 and increase the expression of IL-10 and TGF- $\beta$  (Fernandez-Boyanapalli et al., 2010; Ahmadian et al., 2013; Pisani et al., 2014). Most importantly, however, is pioglitazone role on attenuating the progression of IBDs, as demonstrated by experimental animal models, where treatment of animals induced to development of IBD causes prevention of weight loss, mucosal healing and epithelium restructuration via increase of ZO-1 and claudin-5; pioglitazone also attenuates overall inflammation by reducing NF- $\kappa$ B activation, secretion of cytokines (such as IL-2, TNF $\alpha$  and IL-17) and myeloperoxidase activity (Takagi et al., 2002; Takaki et al., 2006; Da Silva et al., 2018; El Awdan and Mostafa, 2018; Huang et al., 2020).

Even though several animal studies evidence the beneficial role of pioglitazone on treatment and remission of IBDs, the few studies involving pioglitazone and other PPAR $\gamma$  ligands on humans, while conducted to some success, at the end have failed to advance to further stages of clinical trials or relied only on *in silico* approaches (Liang and Ouyang, 2008; Abedi et al., 2015). AnxA1 expression is associated with progression of inflammation in both IBD models and in patients, and previous findings from our group evidenced AnxA1 plays a role on PPAR $\gamma$  activation and actions (da Rocha et al., 2019). Therefore, we aimed to investigate whether AnxA1 could play a role on pioglitazone-mediated resolution of inflammation in an IBD model in order to elucidate how pioglitazone ameliorates disease progression.

## MATERIAL AND METHODS

### In Vivo Experimentation

#### Animals Used

Wild type (WT) or knockout annexin A1 (*AnxA1*<sup>-/-</sup>) male C57Bl/6 mice were obtained from the Center for Development of Experimental Models for Biology and Medicine, Federal University of São Paulo (CEDEME/UNIFESP). Animals were kept under 12 h light/dark cycles at 25°C and were given water and feed *ad libitum*. Experiments were carried in accordance with Ethical Principles for Animal Experimentation (COBEA) and were approved under protocol no. 577 by the Ethics Committee on Animal Use of the Faculty of Pharmaceutical Sciences of the University of São Paulo (CEUA/FCF/USP).

#### Experimental Colitis and Pharmacological Treatment

Acute colitis was induced by ingestion of dextran sodium sulfate (DSS) 40 kDa (Dextran Products Limited, Scarborough, ON, Canada) administered to the drinking water of mice. Throughout a period of 6 days mice consumed water containing 2% DSS 40 kDa, replaced every 2 days so DSS consumption would be homogeneous (de Paula-Silva et al., 2016).

WT and *AnxA1*<sup>-/-</sup> mice were divided in the following groups: 1) Control (drinking water with no other additives), 2) DSS and 3) DSS + pioglitazone. All mice received daily injections of either pioglitazone (Sigma-Aldrich, St. Louis, MO, United States) at a dose of 10 mg/kg or its vehicle (0.9% sterile saline +0.5% carboxymethylcellulose, Sigma-Aldrich, St. Louis, MO, United States). Pioglitazone was prepared in vehicle suspension and sonicated in a sonic bath USC 800<sup>®</sup> (Unique, Indaiatuba, SP, Brazil) for 30 min. A volume of 200  $\mu$ l of the pioglitazone suspension was injected intraperitoneally into mice. The experimental protocol was based on previous works from our research group (Santin et al., 2013; de Paula-Silva et al., 2016). A graphical representation of the experimental protocol is described in Supplementary Material (Supplementary Figure S1).

#### Evaluation of Clinical Parameters

Clinical parameters of animals were verified daily during induction and progression of colitis. Animals were weighted; consistency of feces was determined by collecting a piece of stool and pressing it with forceps in order to verify its softness/hardness; rectal blood was assessed on feces tested for occult blood. For detection of occult blood, a piece of stool was dispersed into 150  $\mu$ l of 0.9% saline solution alongside 150  $\mu$ l of a benzidine (Sigma-Aldrich, St. Louis, MO, United States) and hydrogen peroxide (Synth, Diadema, SP, Brazil) solution; the resulting greenish solution was scored according to its intensity. All mentioned parameters were scored from 0 to 4 as follows (0) weight loss inferior to 1%, solid feces, absence of occult blood (Mak et al., 2020); weight loss ranging from 1 to 5%, slightly softened feces, small amount of occult blood (Luther and Dave, 2020); weight loss ranging from 5 to 10%, softened feces, moderate amount of occult blood (Xu et al., 2018); weight loss ranging from 10 to 20%, pastry feces, considerable amount of

occult blood (Duijvestein et al., 2018); weight loss superior to 20%, liquid feces, high amount of occult blood. Scores were summed at each day, resulting in the disease Activity Index (DAI) (Chassaing et al., 2014).

#### Euthanasia of Mice and Collection of Biological Material

At the end of the experimental model, mice were euthanized by inhalation of isoflurane (BioChimico, Itatiaia, RJ, Brazil) followed by cervical dislocation, as preconized by Norm no. 37 of the National Council for Control of Animal Experimentation (CONCEA). Only after complete inactivity of the animals biological material and tissues were collected. Colons of animals were removed from the ileocecal junction up to the anus, washed and measured; the material was then processed and fragmented, the distal colon being used for histological analyses and the medium/proximal colon being used for protein analyses (Geboes et al., 2000; de Paula-Silva et al., 2016).

#### Processing of Histological Sections

Distal colon fragments harvested from mice were kept overnight in 4% paraformaldehyde (Synth, Diadema, SP, Brazil) at -4°C. For processing, samples were placed in plastic cassettes and washed with decreasing polarity solutions for 1 h each for dehydrating as follows: 70% ethanol, 95% ethanol, absolute ethanol (3x) and xylol (2x) (Synth, Diadema, SP, Brazil). Afterward, samples were embedded in paraffin (Merck, Darmstadt, HE, Germany) pre-heated at 60°C. Then, 5  $\mu$ m serial histological sections were obtained using a microtome (Leica Biosystems, Wetzlar, HE, Germany) and placed upon poly-lysine treated slides (Sigma-Aldrich, St. Louis, MO, United States). Prior to staining, slides were deparaffinized by pre-heating at 60°C, washed and rehydrated.

#### Histological Analyses of the Colon

Deparaffinated and hydrated slides were stained with filtered Harris hematoxylin (Sigma-Aldrich, St. Louis, MO, United States) for 2 min; slides were washed with 80% ethanol and then stained with filtered eosin for 1 min. After washing with distilled water, slides were dehydrated and mounted using a coverslip and Entelan<sup>®</sup> (Sigma-Aldrich, St. Louis, MO, United States).

For histological analysis, slides were assessed with a high-power objective ( $\times 40$ ) in a Zeiss Axio Imager 2<sup>®</sup> microscope (Carl Zeiss, Oberkochen, WB, Germany) and the images obtained were processed using Zeiss Zen<sup>®</sup> software (Carl Zeiss, Oberkochen, WB, Germany). Histological evaluation was performed in a qualitative manner by comparing normal colon histology of control mice with that of DSS-treated animals. Histological parameters assessed were: epithelium integrity and ulceration, loss of crypt structure, presence of edema, hydropic vacuolar degeneration, crypt dysplasia, crypt abscess and presence of inflammatory infiltrate, both in lamina propria and submucosa (Chassaing et al., 2014; de Paula-Silva et al., 2016).

### Immunohistochemical Detection of Annexin A1 and CD68

Deparaffinated and hydrated slides were placed in citrate buffer at 96°C for 30 min. Endogenous peroxidase activity was blocked with 12% hydrogen peroxide (Synth, Diadema, SP, Brazil) for 30 min. Blocking of unspecific epitopes and tissue permeabilization was carried out by incubating the sections with tris-buffered saline (Tris-HCl buffer 200 mM, sodium chloride 1.37 M, all from Synth, Diadema, SP, Brazil) containing 10% bovine serum albumin (Sigma-Aldrich, St. Louis, MO, United States) and 0.1% Tween-20 (Synth, Diadema, SP, Brazil) (TBS-BSA). Then, two serial sections of a same organ were incubated overnight at 4°C with either polyclonal primary anti-annexin A1 (Invitrogen, Waltham, MA, United States) or anti-CD68 (Abcam, Cambridge, CBE, United Kingdom) antibodies at dilutions of 1/250 and 1/25, respectively, diluted in TBS-BSA. Negative controls incubated only with TBS-BSA were also prepared. Then, slides were washed with TBS-BSA and incubated with anti-IgG secondary antibodies conjugated with horseradish peroxidase (HRP) (Invitrogen, Waltham, MA, United States) (Abcam, Cambridge, CBE, United Kingdom) at an 1/200 dilution for 1 h. The sections were washed with TBS-BSA and positive staining was detected using 3,3'-diaminobenzidine (DAB) (Sigma-Aldrich, St. Louis, MO, United States) for a period of 1.5 min. Then, sections were counterstained with hematoxylin (Sigma-Aldrich, St. Louis, MO, United States) and finally mounted with Entellan® (Sigma-Aldrich, St. Louis, MO, United States) under a coverslip.

Immunohistochemical analysis was carried out using a Zeiss Axio Imager 2® microscope (Carl Zeiss, Oberkochen, WB, Germany) and the images obtained were processed using Zeiss Zen software (Carl Zeiss, Oberkochen, WB, Germany). First at a lower power magnification ( $\times 10$ ) slides were screened for "hot spots" areas of CD68<sup>+</sup> cells, which were identified as brownish-yellow stained cells of monocyte/macrophage-like morphology. Using then higher power magnification ( $\times 100$ ), these cells were counted in a total of twelve 0.2 mm<sup>2</sup> fields and averaged. Next, in corresponding areas in adjacent serial sections the intensity of DAB signal related to AnxA1 staining was determined in an arbitrary scale ranging from 0 to 255. Image processing, counting of cells and determination of intensity of DAB staining were carried out using ImageJ® software (Rueden et al., 2017).

### Culturing of Explants and Quantification of Cytokines and MMP-9

Colonic tissue fragments obtained at the end of the experimental model were washed with sterile 0.9% saline solution so debris were removed and placed in 24-well plates in 1 ml of Dulbecco's Modified Eagle's Medium (DMEM) (Vitrocell Embriolife, Campinas, SP, Brazil) containing 10% of fetal bovine serum (FBS) (Vitrocell Embriolife, Campinas, SP, Brazil) and 0.1% of antibiotics (streptomycin, amphotericin and penicillin) (Vitrocell Embriolife, Campinas, SP, Brazil). Explants remained in culture at 37°C under controlled 5% CO<sub>2</sub> atmosphere for a 24 h period. Next, the supernatant culture medium was collected and used for quantification of TNF $\alpha$ , IL-10 and metalloproteinase-9 (MMP-9) via enzyme-linked immunoassay (ELISA). Analysis was carried

out using BD Opteia® and DuoSet® commercial kits according to manufacturer instructions (BD Biosciences, Franklin Lakes, NJ, United States) (R&D Systems, Minneapolis, MN, United States).

### Processing of Colonic Tissue and Western Blotting Analysis

Fragments of the colonic tissue collected at the end of the conducting of the experimental model were immersed in 200  $\mu$ l of radioimmunoprecipitation assay (RIPA) buffer (Tris-HCl buffer 50 mM pH 7.4, sodium deoxycholate 0.5%, dodecyl sodium sulfate 0.1%, sodium chloride 150 mM, all from Synth, Diadema, SP, Brazil) containing protease inhibitors (Sigma-Aldrich, St. Louis, MO, United States) and then processed using a tissue homogenizer T10-Basic Ultra-Turrax® (IKA, Staufen, BW, Germany). The resulting suspensions were centrifuged at 5,000 g in a Sorvall ST 8R centrifuge (Thermo Fisher Scientific, Waltham, MA, United States) for 5 min for removal of non-fragmented tissue. The resulting solutions were sonicated in a Vibra-Cell VCX 500 sonic bath (Sonics, Newtown, CT, United States) for complete cell lysis. The amount of protein in the homogenates was quantified via Bradford assay (Bradford, 1976). Protein homogenates were kept at -80°C until further Western Blotting tests were carried out.

Colon tissue homogenates were subjected to protein separation by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS/PAGE) in 12% polyacrylamide gels at 100 V for 90 min; proteins were then transferred to a polyvinylidene fluoride (PVDF) membrane (Merck, Darmstadt, HE, Germany) at 400 mA for 120 min. Membranes were blocked with a solution of TBS containing 5% BSA (Sigma-Aldrich, St. Louis, MO, United States) and then incubated with either primary anti-AnxA1 antibody (Invitrogen, Waltham, MA, United States) or primary anti-PPAR $\gamma$  antibody (Thermo Fisher Scientific, Waltham, MA, United States), both at an 1/1,000 dilution, overnight at 4°C. The membranes were then washed with TBS and incubated with secondary anti-rabbit HRP conjugated antibody (Invitrogen, Waltham, MA, United States, Cat. NA9340V) at a 1/5,000 dilution for 120 min. Proteins were assessed by chemiluminescence using enhanced-chemiluminescent reagents WestPico SuperSignal® (Thermo Fisher Scientific, Waltham, MA, United States), in an Amersham Imager 600® (GE Healthcare, Chicago, IL, United States). Band intensities were quantified using ImageJ® and are expressed as normalized optometric density units relative to  $\beta$ -actin (Sigma-Aldrich, St. Louis, MO, United States) protein levels. All Western Blotting equipment used was from Bio-Rad (Bio-Rad, Hercules, CA, United States).

### In Vitro Experimentation

#### Cell Lines Used

RAW 264.7 cells (immortalized murine macrophages) were obtained from the Rio de Janeiro Cell Bank (BCRJ), Rio de Janeiro, RJ, Brazil) and cultured in DMEM high glucose medium (4,500 pg/ml) containing 10% FBS and 1 mM sodium pyruvate (all from Vitrocell Embriolife, Campinas, SP, Brazil). Cells were kept at 37°C under controlled CO<sub>2</sub> atmosphere of 5%. Cell medium was changed every 2–3 days and cells were

subcultured every 4–5 days when cells were about to become fully confluent using trypsin 0.01% containing 0.02% ethylenediamine tetra acetic acid (EDTA) (all from Vitrocell Embriolife, Campinas, SP, Brazil).

#### Knockdown of AnxA1 Expression in Macrophages

Knockdown of AnxA1 on RAW 264.7 cells was carried out using commercial Mission<sup>®</sup> pLKO.1 plasmids (#Addgene 10,878) containing four different short-hairpin RNA (shRNA) sequences designed to be complementary to the 3'-UTR murine AnxA1 mRNA sequence (Sigma-Aldrich, St. Louis, MO, United States). Transformed *E. coli* purchased in glycerol stocks were grown according to manufacturer instructions (Sigma-Aldrich, St. Louis, MO, United States).

Plasmids were purified from culture medium containing transformed bacteria using the commercial kit PureLink HiPure Plasmid Maxiprep (Thermo Fisher Scientific, Waltham, MA, United States), according to manufacturer instructions. After purification, plasmid concentration was assessed using a Nanodrop 2000 spectrophotometer (Thermo Fisher Scientific, Waltham, MA, United States).

HEK293FT cells (renal embryo cells, American Type Culture Collection, Manassas, VA, United States) were plated on 10 cm dishes at a density of  $2 \times 10^6$  cells per plate and cultured with DMEM containing 10% FBS, 1 mM sodium pyruvate and 1 mM glutamine (Vitrocell Embriolife, Campinas, SP, Brazil) at 37°C under controlled CO<sub>2</sub> atmosphere of 5%. Once cells reached 80% confluence, they were washed and culture medium was renewed with medium containing 25 μM chloroquine (Sigma-Aldrich, St. Louis, MO, United States), which remained on the cells for 30 min. After this period, these cells were transfected by calcium phosphate precipitation. For such, 3 μg of each accessory plasmid (pRSV rev, pMDLg/pRRE and pHCMV-G), 0.5 μg of fluorescence reporter plasmid (pEGFP) and 8 μg of the control plasmids (pLKO.1 empty vector and a plasmid containing scrambled, non-functional sequence, used for mock-transfection) or shRNA plasmids (Mission<sup>®</sup> pLKO.1 AnxA1 shRNA plasmid, Sigma-Aldrich, St. Louis, MO, United States) were added to 500 μl of a 0.25 M CaCl<sub>2</sub> solution. After that, 500 μl of HEPES Buffer Saline 2X (280 mM NaCl, 1.5 mM Na<sub>2</sub>HPO<sub>4</sub> and 50 mM HEPES; pH 7.0, all from Synth, Diadema, SP, Brazil) were added to the transfection mixture while vortexing and then allowed to rest for 6 h. HEK293FT cells were incubated for 6 h in culture medium containing 25 μM of chloroquine and the transfection mixture. At the end of this period, culture medium was renewed and the cells remained in incubator at 37°C under 5% CO<sub>2</sub> for further 42 h. Forty-eight hours after transfection, the supernatants containing lentiviral particles were harvested, centrifuged at (3,000 rpm for 15 min) and filtered using 0.45 μm filters. All procedures involving manipulation of lentiviral material were carried out following special safety regulations as preconized by Brazilian health and safety laws.

RAW 264.7 cells were previously plated in 6-well plates at a density of  $2 \times 10^5$  cells per well for lentiviral transduction and cultured as described in item 2.2.1. These cells were incubated with a solution of renewed media, containing 1:3 (2 ml per well) diluted virus and supplemented with 10 μg/ml of polybrene

(EMD Millipore, Billerica, MA, United States). RAW 264.7 cells were kept in incubation for 24 h at 37°C under controlled CO<sub>2</sub> atmosphere. Puromycin (Santa Cruz Biotechnology, Dallas, TX, United States) was added to the culture medium at a final concentration of 7 μg/ml for 48 h for selection of stable transduced cells.

After puromycin selection, a total of  $5 \times 10^5$  cells were lysed in 50 μl of RIPA buffer containing protease inhibitors; Western Blotting procedure for validation of AnxA1 knockdown was identical to the procedure described in item 2.1.9. Out of the four shRNA sequences tested, the one which led to most efficient AnxA1 knockdown was selected to be used for all further experiments. The growth of mock-transfected and AnxA1-knockdown cells was assessed daily by manual counting for 7 days and compared to the growth of wild type RAW 264.7 cells.

Information regarding shRNA sequences used, AnxA1 knockdown efficiency and cell growth rates are detailed in Supplementary Material (Supplementary Figure S2).

#### Cell Treatments

RAW 264.7 cells were cultured as described in item 2.2.1. For experimentation, cells were cultured in 24-well plates at a density of  $2 \times 10^5$  cells/well (for flow cytometry and ELISA tests) or in 12-well plates at a density of  $5 \times 10^5$  cells/well (for Western Blotting tests). After cells had adhered, the culture medium was replaced with fresh medium and cells were treated.

Cells were treated with pioglitazone, a specific PPAR $\gamma$  ligand, at a concentration of 10 μM (Sigma-Aldrich, St. Louis, MO, United States) for 24 h. *E. coli* lipopolysaccharide 026:B6 at a concentration of 1 μg/ml was added to the cells 1 h after pioglitazone was added. For specific experiments, cells were also treated with GW9662, a PPAR $\gamma$  antagonist, at a concentration of 10 μM (Tocris, Bristol, BRS, United Kingdom) for 30 min prior to treatment with pioglitazone. Control cells were treated only with the vehicle used for solubilization of pioglitazone, 0.1% dimethyl sulfoxide (DMSO) (Synth, Diadema, SP, Brazil).

At the end of each treatment, supernatants from the culture medium were collected and stored at -80°C until further ELISA tests and cells were washed with phosphate buffer saline (PBS) and harvested with trypsin 0.01% containing 0.02% EDTA (all from Vitrocell Embriolife, Campinas, SP, Brazil) for either flow cytometry or Western Blotting tests.

Details of the experimental protocol for cell treatment are graphically described in Supplementary Material (Supplementary Figure S3).

#### Assessment of Cytokine and MMP-9 Secretion

After treatments, cell supernatants were collected for assessment of cytokine and MMP-9 secretion via ELISA. Quantification was carried out using commercial ELISA kits following manufacturer instructions (BD Biosciences, Franklin Lakes, NJ, United States). TNF $\alpha$  and IL-10 cytokines were assessed.

#### Assessment of ROS Production and Expression of Surface Markers

After treatments, cells were collected and production of reactive oxygen species (ROS) and expression of adhesion molecules and

of formyl peptide receptors 1 and 2 (FPR1 and FPR2) on cell surface were assessed via flow cytometry. For assessment of reactive oxygen species (ROS) production,  $5 \times 10^4$  cells were separated from the total amount of treated cells, washed with PBS and incubated with 0.3 mM dichlorofluorescein diacetate (DCFH-DA) (Sigma-Aldrich, St. Louis, MO, United States) solution diluted in PBS. Cells were kept at 37°C under controlled CO<sub>2</sub> atmosphere of 5% for 30 min. After this incubation period, cold PBS was added to the cells. Lastly, cells were taken to an Accuri C6<sup>®</sup> flow cytometer (BD Biosciences, Franklin Lakes, NJ, United States) and a minimum of 10,000 events were acquired per sample. For assessment of cell surface adhesion molecules,  $2 \times 10^5$  cells were plated, treated, collected, washed with PBS and incubated with phycoerythrin-labeled (PE) anti-CD54 (BD Biosciences, Franklin Lakes, NJ, United States, Cat. 553263) or PE-labeled anti-CD62L (BD Biosciences, Franklin Lakes, NJ, United States, Cat. 553151), both at a 1/100 dilution in PBS, for 30 min. The protocol was the same for assessment of FPR1 and FPR2, but cells were incubated with either fluorescein isothiocyanate (FITC) labeled anti-FPR2 antibody (Bioss, Woburn, MA, United States) for 30 min or primary anti-FPR1 antibody (CliniSciences, Nanterre, IDF, France) for 2 h, both at a 1/100 dilution; cells previously incubated with anti-FPR1 antibody were washed with PBS and incubated with PE-labeled anti-IgG secondary antibody (Abcam, Cambridge, CBE, United Kingdom) at a 1/200 dilution for 30 min. Lastly, cells were again washed and taken to an Accuri C6<sup>®</sup> flow cytometer (BD Biosciences, Franklin Lakes, NJ, United States) and a minimum of 10,000 events were acquired per sample.

#### Assessment of AnxA1 Expression and Cleaving and PPAR $\gamma$ Expression

For assessment of AnxA1 cleaving, cells were harvested after treatments as described in item 2.2.3 and cell lysates were prepared using RIPA buffer containing protease inhibitors; quantification of protein content via Bradford assay and Western Blotting analyses of quantification of AnxA1 and of assessment of AnxA1 cleaving were carried out as described in item 2.1.9.

For assessment of AnxA1 and PPAR $\gamma$  expression, cells were harvested, fixed with 4% paraformaldehyde for 30 min (Synth, Diadema, SP, Brazil), washed with 0.1 M glycine (Synth, Diadema, SP, Brazil) and permeabilized with 0.01% Triton-X for 30 min (Sigma-Aldrich, St. Louis, MO, United States). Cells were washed with PBS between all steps. Then, cells were incubated overnight with either primary anti-AnxA1 (BD Biosciences, Franklin Lakes, NJ, United States) or anti-PPAR $\gamma$  (Thermo Fisher Scientific, Waltham, MA, United States) antibodies in a 0.1% BSA and 0.01% sodium azide solution (Thermo Fisher Scientific, Waltham, MA, United States) at a 1/100 dilution for either. Cells were then washed and incubated with PE conjugated secondary anti-IgG antibody at a 1/200 dilution for 30 min. Cells were then taken to an Accuri C6<sup>®</sup> flow cytometer (BD Biosciences, Franklin Lakes, NJ, United States) and a minimum of 10,000 events were acquired.

#### Assessment of ERK Phosphorylation

Phosphorylation of extracellular signal-regulated kinase (ERK) proteins was carried out via flow cytometry. Mock-transfected and AnxA1-knockdown RAW 264.7 cells were harvested after treatments and processed the same manner as described in item 2.2.3. Cells were incubated overnight with primary anti-ERK1/2 and anti-pERK1(Thr202)/2(Thr185) antibodies (BD Biosciences, Franklin Lakes, NJ, United States) at 1/100 and 1/200 dilutions, respectively. Cells were then washed and incubated with FITC and PE conjugated secondary anti-IgG antibodies at dilutions 1/200 for 30 min. Finally, cells were taken to an Accuri C6<sup>®</sup> flow cytometer (BD Biosciences, Franklin Lakes, NJ, United States) and a minimum of 10,000 events were acquired.

#### Statistical Analysis

Data were analyzed using GraphPad Prism seven software (Graphpad Software<sup>®</sup>, San Diego, CA, United States). For analysis of clinical parameters two factor analysis of variance tests (Two-Way ANOVA) followed by Bonferroni post-hoc tests were performed. For comparison between number of stained macrophages and intensity of AnxA1 signal in DAB-stained tissue sections, linear regressions followed by Pearson's correlation tests were performed. For all other experiments performed, data were analyzed using when appropriate either Student's *t* tests or one factor analysis of variance (One-Way ANOVA) followed by Tukey post-hoc tests in order to assess differences between the evaluated groups. Differences between assessed means and correlation coefficients were considered statistically significant assuming  $p < 0.05$ . All results are shown as mean  $\pm$  standard-error of the mean.

## RESULTS

### Pioglitazone Treatment Attenuates Dextran Sodium Sulfate-Induced Colitis Progression of Wild Type, but Not AnxA1<sup>-/-</sup> Mice

Clinical manifestations of DSS-induced colitis were assessed as body weight loss, rectal bleeding and consistency of feces, their sum resulting in a greater DAI in DSS-treated than control mice. All these disease parameters were even more pronounced in AnxA1<sup>-/-</sup> mice, confirming AnxA1<sup>-/-</sup> mice are more susceptible to damage caused by DSS (Babbini et al., 2008; Leoni et al., 2015; de Paula-Silva et al., 2016). The intraperitoneal administration of pioglitazone reduced body weight loss and increased feces consistency between days 2 and 4 of the disease in WT mice. Pioglitazone treatment did not attenuate clinical parameters of colitis in AnxA1<sup>-/-</sup> mice, and disease scores remained comparable to that of non-treated animals (Figures 1A–D). These data evidence pioglitazone attenuates the development of DSS-induced colitis in an AnxA1 dependent manner.

Also, in order to verify whether these beneficial clinical effects caused by pioglitazone treatment could be influenced or not by AnxA1 knockdown or by DSS intake due to changes in PPAR $\gamma$  expression, PPAR $\gamma$  expression was assessed in tissue homogenates from colon fragments. PPAR $\gamma$  expression in AnxA1<sup>-/-</sup> mice was

found to be at the same levels of WT mice, regardless of any treatments, thus showing any effects on clinical parameters (and on all other further effects described *in vivo*) caused by pioglitazone treatment in mice were likely not influenced by changes in PPAR $\gamma$  expression (Supplementary Figure S4).

### Pioglitazone Treatment Preserves Colon Extension and Histoarchitecture of Wild Type, but Not *AnxA1*<sup>-/-</sup> Mice

The extension of large intestines of DSS-treated mice was significantly reduced in comparison to samples of control mice. Pioglitazone treatment attenuated such reduction only in WT mice, as intestines harvested from DSS treated *AnxA1*<sup>-/-</sup> mice treated with pioglitazone had the same extension as *AnxA1*<sup>-/-</sup> mice which received DSS only (Figures 2A,B). These data corroborate the findings related to assessment of clinical parameters confirming pioglitazone treatment halts DSS-induced colitis progression in WT but not in *AnxA1*<sup>-/-</sup> mice.

Histopathological analyses of intestines showed administration of DSS induced tissue injuries not observed in control mice, which resemble those found in human IBD (Perse and Cerar, 2012) (Figures 2C–E). DSS administration caused loss of tissue structure alongside ulcerations, loss of crypt structure, presence of

edema and of inflammatory infiltrates, crypt abscesses, crypt dysplasia and vacuolar hydropic degeneration. Such effects were more pronounced in *AnxA1*<sup>-/-</sup> mice (Figures 2F–H). Pioglitazone treatment attenuated loss of tissue morphology in WT mice, as there was less edema and crypts were still preserved to some extension (Figure 2E). Beneficial effects of pioglitazone treatment were not observed in tissue sections of DSS-treated *AnxA1*<sup>-/-</sup> mice (Figure 2H). In association with clinical parameters, these findings show pioglitazone preserves colon histoarchitecture and reduces damage caused by DSS administration, the presence of *AnxA1* being an important role player for such effects.

### Inhibitory Effects of Pioglitazone on Secretion of Inflammatory Cytokines by Colon Tissue Is Modulated by *AnxA1*

Analysis of inflammatory cytokines evidenced increased secretion of TNF $\alpha$  and IL-10 from WT or *AnxA1*<sup>-/-</sup> inflamed colon explants. Treatment with pioglitazone reduced the secretion of both cytokines from colon explants of WT mice, but not from colon explants of *AnxA1*<sup>-/-</sup> mice, suggesting pioglitazone relies on expression of *AnxA1* to attenuate the secretion of inflammatory cytokines (Figures 3A–D). These data, altogether with those describing assessment of clinical parameters, intestine extension and colon

histoarchitecture, evidence pioglitazone treatment modulates the development of DSS induced colitis in an AnxA1 dependent manner.

### Pioglitazone Prevents Cleaving of AnxA1 in Colon Tissue

As it was evidenced AnxA1 is necessary for the anti-inflammatory effects of pioglitazone on DSS-induced colitis, its expression and

cleaving status were assessed in WT mice. DSS administration increased expression of AnxA1 in the inflamed colon, regardless of treatment with pioglitazone (Figure 4A; Supplementary Figures S5A–D). However, pioglitazone treatment prevented AnxA1 cleaving into non-functional 33 kDa fragments, preserving whole the functional 37 kDa protein (Figure 4B; Supplementary Figures S5A–D). Also, while DSS-treatment increased the expression of MMP-9 as assessed in colon tissue homogenates, treatment with

pioglitazone decreased such expression (Figure 4C). These data demonstrate pioglitazone treatment preserves the structure of full length 37 kDa AnxA1 and decreases the expression of MMP-9 induced by DSS, which was previously shown to be involved with AnxA1 cleaving in mice intestinal epithelial cells (Leoni et al., 2015).

#### Dextran Sodium Sulfate-Induced Colitis Promotes Recruitment of AnxA1-Releasing Macrophages Regardless of Pioglitazone Treatment

Analysis of colon sections showed higher number of CD68<sup>+</sup> macrophages in the colon of DSS-treated mice in comparison to control mice, regardless of treatment with pioglitazone (Figures 5A–C,G). Corresponding areas in serial sections assessed for AnxA1 staining evidenced a greater presence of this protein in tissue sections from DSS-treated mice in comparison to tissue sections from control mice; such increased staining corresponding to AnxA1 also was not influenced by pioglitazone treatment (Figures 5D–F,H). Correlation analysis associated AnxA1 expression with increased number of CD68<sup>+</sup> macrophages (Figures 5I–K). These findings allow us to suggest DSS colitis leads to recruitment of AnxA1-releasing CD68<sup>+</sup> macrophages and also increases AnxA1 secretion, and such events are unaffected by pioglitazone treatment.

#### Lipopolysaccharide-Induced Inflammatory Parameters Are Attenuated by Pioglitazone in RAW 264.7 Macrophages Relying on AnxA1 Expression

The generation of AnxA1 knockdown RAW 264.7 cells and further stimulation with LPS was the strategy employed to investigate the role of AnxA1 on pioglitazone-mediated anti-inflammatory effects and the actions of pioglitazone on cleaving of AnxA1 in macrophages. LPS treatment increased the generation of ROS and secretion of TNF-α and IL-10 by

RAW 264.7 macrophages. These parameters were attenuated in mock-transfected cells treated with pioglitazone, but not in AnxA1-knockdown transfected cells (Figures 6A–C). LPS treatment also increased surface expression of CD54 and CD62L, which was reversed by treatment with pioglitazone in mock-transfected cells but not in AnxA1-knockdown cells (Supplementary Figures S6A,B). Thus, these data evidence AnxA1 is key for the anti-inflammatory effects of pioglitazone on macrophages, corroborating our *in vivo* data in an isolated *in vitro* system.

Following a similar rationale as investigated in mouse tissue, PPARγ expression was verified as to assess whether changes on it would influence anti-inflammatory outcomes exerted by pioglitazone treatment. Unlike the results seen in mouse tissue, PPARγ expression increased due to LPS treatment, regardless of actions of pioglitazone, but only in mock-transfected RAW 264.7 cells (Supplementary Figure S7A). Further analysis under non-inflammatory conditions revealed pioglitazone induced PPARγ expression as expected in mock-transfected cells but not in AnxA1-knockdown cells (Supplementary Figure S7B). These findings evidence that functional expression of AnxA1 is required for pioglitazone to exert its actions and induce PPARγ expression.

#### Pioglitazone Prevents the Cleaving of AnxA1 in RAW 264.7 Macrophages

In the same vein as seen *in vivo*, inflammation caused by LPS increased AnxA1 expression in wild type RAW 264.7 cells, effect not reversed by treatment with pioglitazone (Figure 7A). LPS also caused AnxA1 cleaving into 33 kDa fragments, while pioglitazone prevented such cleaving (Figure 7B; Supplementary Figures S8A–J). LPS treatment also increased MMP-9 expression, and pioglitazone treatment did prevent such increase (Figure 7C). Thus, corroborating our *in vivo* data, pioglitazone is unable to control AnxA1 expression in inflammatory conditions, but can modulate its functionality by preventing its cleaving.

### Pioglitazone Actions Are PPAR $\gamma$ -Dependent in RAW 264.7 Macrophages

As it was determined PPAR $\gamma$  expression increased due to treatment with pioglitazone in mock-transfected cells, we investigated whether anti-inflammatory effects seen so far in AnxA1-expressing RAW 264.7 cells would be abrogated due to blocking of PPAR $\gamma$ . Increased levels of TNF $\alpha$  and MMP-9 induced by LPS were attenuated by treatment with pioglitazone, but not when cells have been previously treated with GW9662 (Supplementary Figures S9A,B). This evidences the anti-inflammatory actions of pioglitazone, at least those here assessed, are likely dependent on PPAR $\gamma$  activation.

### AnxA1 Is Required for ERK Phosphorylation Induced by Pioglitazone in RAW 264.7 Macrophages

ERK phosphorylation is a *downstream* pathway event following AnxA1 binding to its receptors and pioglitazone can induce ERK phosphorylation. Hence, we investigated ERK phosphorylation as a possible factor connecting the anti-inflammatory actions of pioglitazone and AnxA1. Indeed, ERK phosphorylation was increased in mock-transfected RAW 264.7 cells treated with pioglitazone, but not in AnxA1-knockdown cells, meaning *downstream* signaling after PPAR $\gamma$  activation requires expression of functional AnxA1 (Figure 8A). Expressions of FPR1 and FPR2, G-protein coupled receptors known to bind to AnxA1 and exert downstream signaling, of which FPR2 is the better described for anti-inflammatory effects of AnxA1, did not change due to treatment with pioglitazone in either mock-transfected or AnxA1-knockdown cells, but FPR2 expression was overall higher in AnxA1-knockdown cells, likely as a cell response to low levels of AnxA1 (Figures 8B,C). Thus, while pioglitazone does not necessarily modulate FPR2 expression, the lack of AnxA1, which is needed for ERK activation via FPR2, induces its expression.

## DISCUSSION

Research on IBD therapy has advanced on the past few years, and inflammatory cytokines or specific cellular pathways such as JAK/STAT and phosphodiesterase-4 have all been explored as potential targets for IBD treatment (Pekow, 2017). Still, it is unlikely that a significant number of such newly-developed drugs aimed at interacting with the aforementioned targets will reach clinical practice, as several of these compounds do not display satisfactory remission rates or lead to severe adverse effects, such as increased risk for infection, malignancies or immunological disorders in larger clinical trials (Pekow, 2017; Click and Regueiro, 2019).

Thus, the search for drugs for treatment of IBDs has taken scientists to explore molecules beyond those designed to specifically treat IBDs and reassess drugs originally developed to treat other maladies (Lloyd et al., 2019; Kostoff et al., 2020). Such is the case of thiazolidinediones, PPAR $\gamma$  ligands originally

developed for treatments of diabetes, which have been explored to some success for treatment of IBDs. While clinical trials on PPAR $\gamma$  ligands seem somewhat promising, obtaining of conclusive results which could take research steps further on drug repurposing has been elusive so far (Lewis et al., 2008; Liang and Ouyang, 2008; Abedi et al., 2015).

While mechanisms unveiling how thiazolidinediones ameliorate IBD progression are yet to be completely understood, data on AnxA1 roles on IBD suggest it might be a promising player on the actions of PPAR $\gamma$  ligands leading to anti-inflammatory effects. Indeed, our research group has evidenced AnxA1 is vital for infliximab actions on murine IBD models (de Paula-Silva et al., 2016) and that AnxA1 is a promising biomarker for assessing responsiveness to infliximab in human IBD patients (unpublished observations). We have also shown both exogenous and endogenous AnxA1 are required for pioglitazone to induce BV2 microglia cells to phagocytize apoptotic cells, and that AnxA1 can modulate PPAR $\gamma$

expression in such cells (da Rocha et al., 2019). Data here obtained confirm the connection between pioglitazone and AnxA1 on treatment of experimental colitis, evidencing the inhibition of AnxA1 cleaving into its inactive form as a mechanism of action of pioglitazone; therefore, we suggest AnxA1 is as a key player required for the anti-inflammatory actions of pioglitazone and thus possibly other PPAR $\gamma$  ligands.

Data here obtained corroborated other studies which already evidenced the beneficial actions of pioglitazone in murine models of colitis (Saubermann et al., 2002; Takagi et al., 2002; Shah et al., 2007; Huang et al., 2020) and evidenced the lack of pioglitazone effects on AnxA1<sup>-/-</sup> mice demonstrating the pivotal role of AnxA1 for pioglitazone anti-inflammatory actions. However, these data do not rule out the effects of pioglitazone and AnxA1 are independent; inflammation exerted when lacking endogenous AnxA1 could be exceedingly exacerbated, overwhelming any attempts of PPAR $\gamma$ -activation linked mechanisms to halt disease progression. Indeed, DSS-colitis in

AnxA1<sup>-/-</sup> mice is more pronounced and leads to increased mortality (Babbitt et al., 2008; de Paula-Silva et al., 2016) and AnxA1 expression in the colon of WT mice increased regardless

of treatment with pioglitazone. However, we here show pioglitazone prevented cleaving of AnxA1 whole 37 kDa form into smaller 33 kDa fragments, which are supposedly non-functional and induce inflammation, as evidenced in other models where AnxA1 cleaving correlates with increased inflammatory status in neutrophils (Vong et al., 2007; Williams et al., 2010; Vago et al., 2012; Sugimoto et al., 2016; Vago et al., 2016). AnxA1 can be cleaved at different cells and tissues, such as in neutrophils, adipose tissue and melanomas; non-functional 33-kDa peptides released promote inflammation facilitating cell transmigration to inflamed areas, inducing adipogenesis and causing skin tumors to become more aggressive (Williams et al., 2010; Boudhria et al., 2014; Pietrani et al., 2018). Pioglitazone treatment also reduced MMP-9 expression in the inflamed gut of WT mice. Metalloproteinases such as MMP-9 induce inflammatory damage on tissues by cleaving extracellular matrix proteins, and that by itself can aggravate ulcerative colitis (Marshall et al., 2015; Chen et al., 2017). In this context, MMP-9 also cleaves AnxA1 into inactive 33 kDa proteins under inflammatory conditions (Zamilpa et al., 2010; Sugimoto et al., 2016). It must be noted that PPAR $\gamma$  expression suffered no changes due to DSS treatment or to lack of AnxA1, meaning pioglitazone could bind to its target in colon tissue at similar levels for all experimental conditions. This is in accordance with other authors who also reported PPAR $\gamma$  levels suffer little to no variances in colon tissue throughout the development of DSS colitis (Huang et al., 2020).

Thus, our data suggest that pioglitazone might indeed be linked to AnxA1 in order to exert its anti-inflammatory actions during the progression of DSS-induced colitis, but by modulating its functionality rather than its overall expression. Considering AnxA1 is a strong candidate for predictor of disease remission due to therapies on IBDs and AnxA1 expression levels tend to vary greatly in IBD patients, such information might aid elucidating why clinical trials investigating PPAR $\gamma$  ligands on IBDs tend to fail (Lewis et al., 2001; Lewis et al., 2008).

It is known that lamina propria residential macrophages play an important housekeeping role by phagocytosing apoptotic epithelial cells, clearing translocated bacteria and promoting epithelial stem cell maturation (Na et al., 2019). On the course of IBDs, residential macrophages and recruited monocytes become inflammatory M1 macrophages, which secrete inflammatory cytokines such as TNF $\alpha$ , IL-12, and IL-23 and induce Th1 responses (Bernardo et al., 2017; Na et al., 2019). However, during resolution phases of IBDs, lamina propria macrophages acquire a M2 phenotype and promote tissue repair due to releasing several anti-inflammatory factors such as IL-10 and AnxA1 (Na et al., 2019; Koelink et al., 2020). Macrophages are thus vital for both sustaining intestinal homeostasis and carrying intestinal inflammation, and evidence suggests AnxA1 released by these cells during resolute phases of IBD can be responsible for attenuating disease progression (Vong et al., 2012; Quiros et al., 2017). Also, PPAR $\gamma$  in macrophages plays an important role on IBD physiopathology, as macrophage-specific PPAR $\gamma$  knockdown leads to pronounced colitis clinical effects, accumulation of TCD8+ lymphocytes in lamina propria, increase of CD40

surface expression and secretion of inflammatory cytokines in the intestine (Shah et al., 2007; Hontecillas et al., 2011). Data here obtained show tissue sections from WT mice had a basal counting of CD68<sup>+</sup> macrophages which increased due to DSS administration, regardless of pioglitazone treatment, and indeed, corresponding areas on sections immunostained for AnxA1 evidenced there is a positive correlation between number of CD68<sup>+</sup> macrophages and AnxA1 expression, as both increased proportionally when mice were subjected to development of DSS-induced colitis. Thus, tissue inflammation caused by DSS led to recruitment of AnxA1 secreting monocytes in order to halt inflammation and evoke tissue repair (Steinbach and Plevy, 2014; Na et al., 2019). Other authors have reported increased number of CD68<sup>+</sup> macrophages in tissue sections either from biopsies specimens of Crohn's disease or ulcerative colitis patients or from intestines of DSS-treated mice, corroborating our data (Vong et al., 2012; Hong et al., 2014; Lissner et al., 2015; Reischl et al., 2020). However, studies correlating counting of CD68<sup>+</sup> macrophages with AnxA1 expression report seemingly contradicting evidence. It is reported by authors in biopsies from Crohn's disease patients that AnxA1 expression correlates only with myeloperoxidase-positive neutrophils excluding CD68<sup>+</sup> macrophages in lamina propria (Reischl et al., 2020), but others report the opposite by showing AnxA1 expression correlates with increased CD68<sup>+</sup> counting in tissue biopsies from ulcerative colitis and Crohn's disease patients, in agreement with our findings (Vong et al., 2012). Given the

complexity of IBD as a disease, it is unsurprising contradicting evidence would be found, and our work contributes in elucidating such ambiguities.

While the findings here described utilizing a murine model of experimental colitis so far evidence there is a connection between pioglitazone actions and AnxA1, assessment of AnxA1 as a marker of disease progression under pioglitazone treatment should still be considered in a preliminary manner and approached with due reservations in further studies involving humans. The immune system of mice is quite different from that of humans, and different immune responses in the gut can lead to different inflammatory processes being observed in both experimental colitis and human IBD which are not always similar, such as seen for activation of Treg cells, secretion of cytokines and infiltration of B lymphocytes (Del Prete et al., 1993; Stevceva et al., 2001; Mestas and Hughes, 2004; Gibbons and Spencer, 2011; Neurath, 2014; Wang et al., 2015; Do et al., 2017; Sun et al., 2017). Still, despite there being discrepancies, certain AnxA1 roles described in murine models of experimental colitis are corroborated in human IBD patients, such as infliximab treatment in AnxA1 knockout mice undergoing DSS colitis failing to attenuate disease progression, which links to other findings evidencing infliximab-responsive IBD patients show a greater expression of AnxA1 in colon tissue (Sena et al., 2013; de Paula-Silva et al., 2016). The same is true for PPAR $\gamma$ , as Crohn's disease-like ileitis is prevented in disease-susceptible SAMP/Fe mice crossbred with disease-resistant mice due to inheritance of

functional PPAR $\gamma$  alleles, and certain polymorphisms in the PPAR $\gamma$  gene have been described as prevalent in Crohn's disease patients (Sugawara et al., 2005). In the same vein, a number of drugs used for treatment of IBD in humans have

been successfully validated for use in experimental colitis models in mice (Melgar et al., 2008). Translation between mouse colitis models and human IBD is thus very feasible, but future assessment of mechanisms involving AnxA1 and pioglitazone as described in this work, when in human IBD patients, should therefore consider the aforementioned reservations.

In order to reinforce our *in vivo* data, an *in vitro* experimental protocol was carried out using the RAW 264.7 macrophage cell line. Using LPS to mimic an inflammatory environment, we found that LPS treatment increased secretion of TNF $\alpha$  and IL-10 and generation of ROS, effects abrogated due to treatment with pioglitazone. Corroborating our *in vivo* data, the anti-inflammatory effects of pioglitazone were only detected in mock-transfected cells, but not in AnxA1 knockdown cells, which evidences endogenous AnxA1 is vital for pioglitazone anti-inflammatory effects in macrophages. The same manner as seen in our *in vivo* data, pioglitazone did not modify AnxA1 expression. It has been reported that rosiglitazone and prostaglandin J<sub>2</sub>, both PPAR $\gamma$  ligands, increase AnxA1 expression, but such has been demonstrated in MDA-MB-231 and MCF-7 breast cancer cells to variable results and not at inflammatory conditions (Chen et al., 2017). LPS also increased AnxA1 expression by RAW 264.7 cells and expressed AnxA1 was cleaved into smaller, non-functional 33 kDa fragments, and regardless of the effects of pioglitazone on AnxA1 expression, it prevented AnxA1 cleaving and attenuated secretion of MMP-9. Control of MMP-9 secretion is a known anti-inflammatory effect of pioglitazone and other PPAR $\gamma$  ligands; they can modulate septin-2 in cancer cells preventing MMP-9 actions, and during the course of intestinal inflammations, down-modulation of PPAR $\gamma$  can make MMP-9 more stable (Kundu et al., 2014; Cao et al., 2015). Still, it had not yet been demonstrated that such effect could be linked to prevention of AnxA1 cleaving. As described previously, pioglitazone seems to attenuate inflammation by preventing AnxA1 cleaving rather than controlling its overall expression, and using our *in vitro* model we found evidence that so happens in macrophages, strengthening our *in vivo* data. Of note, contrary to what was seen *in vivo*, inflammatory conditions increased PPAR $\gamma$  expression in mock-transfected but not in AnxA1-knockdown macrophages. Under non-inflammatory conditions, pioglitazone by itself induced PPAR $\gamma$  expression, as expected due to it being a PPAR $\gamma$  ligand, but also only in mock-transfected cells. It is reported LPS activates PPAR $\gamma$  as a means of "desensitizing" macrophages attenuating responses to further inflammatory stimuli, and AnxA1 seems to be involved with such modulation of PPAR $\gamma$  in both inflammatory and non-inflammatory conditions (Von Knethen and Bernhard, 2001). Whether lack of AnxA1 prevents pioglitazone binding to PPAR $\gamma$  or prevents some sort of post-translational mechanism after interaction between PPAR $\gamma$  and a ligand was not assessed in our work, but the fact this interaction was seen in isolated macrophage cultures and not in mice tissue further reinforces the need for *in vitro* models to better investigate specific effects which might become hidden

amid the myriad of simultaneous biological processes occurring *in vivo*. Indeed, PPAR $\gamma$  in colon tissue is expressed not only by lamina propria macrophages, but also at considerable levels by crypt epithelial cells (Su et al., 2007).

While pioglitazone showed its anti-inflammatory effects to be reliant on AnxA1, it is known pioglitazone has other effects that are PPAR $\gamma$ -independent, such as induction of migration of vascular smooth muscle cells and inhibition of proliferation of tumor cells (Emery et al., 2006; Li et al., 2008). By expanding some of the *in vitro* findings previously described, we evidenced some of the anti-inflammatory actions of pioglitazone are indeed PPAR $\gamma$ -dependent, as treatment of RAW 264.7 cells with the PPAR $\gamma$  antagonist GW9662 prevented the increased secretions of TNF $\alpha$  and MMP-9 to be attenuated by pioglitazone. To our knowledge, this effect has been previously described for TNF $\alpha$  in myocytes, but not in RAW 264.7 macrophages (Liu et al., 2009). This is relevant for prospective studies on PPAR $\gamma$  ligands and AnxA1, as knowing that inhibition of MMP-9 secretion is dependent on PPAR $\gamma$  makes it more likely that other PPAR $\gamma$  ligands studied for treatment of IBD would have the same effect in preventing AnxA1 cleaving.

As to further elucidate how AnxA1 could influence the anti-inflammatory effects of pioglitazone, we investigated whether AnxA1 knockdown of RAW 264.7 macrophages could affect pioglitazone-induced phosphorylation of extracellular regulator

kinase (ERK). ERK is a signaling factor linked to several cell processes, such as cell survival, differentiation and migration, among others (Maurice et al., 2018; Li et al., 2019; Zhou et al., 2019), and it is known that pioglitazone can activate ERK1/2 phosphorylation leading to anti-inflammatory effects, as reported on ischemic cardiomyocytes and on different cell lines, including colon cell lines (Wang et al., 2012; Kole et al., 2016). Our data showed that pioglitazone did cause ERK phosphorylation, but such effect was not seen in AnxA1 knockdown cells, evidencing AnxA1 is required for pioglitazone-induced ERK phosphorylation to occur. ERK phosphorylation is also known to take place *downstream* to AnxA1 activation in a plethora of cells, including macrophages (Dufton et al., 2010; Bena et al., 2012). As we evidenced lacking AnxA1 prevents ERK phosphorylation, it can be inferred that AnxA1 might be the sole activator of ERK phosphorylation *downstream* to PPAR $\gamma$  activation in this scenario, being an intermediate molecule connecting pioglitazone actions and ERK phosphorylation, which is allowed to activate ERK by pioglitazone by remaining functional and non-cleaved for longer. In addition, increased FPR2 expression, but not FPR1, in AnxA1-knockdown cells suggests there is a cell response under absence of AnxA1 which aims to increase FPR2-mediated downstream signaling, which is known to involve ERK phosphorylation (Bena et al., 2012) leading to most anti-inflammatory effects of AnxA1, such

as reduction of inflammatory cytokines and of neutrophil activation in different murine models of inflammation (Ding et al., 2020; Machado et al., 2020). Pioglitazone, by preserving full length-AnxA1, thus possibly increases the likelihood for AnxA1 to bind to FPR2 leading to ERK phosphorylation.

Overall, our main findings evidence pioglitazone relies on AnxA1 expressed by macrophages to exert its anti-inflammatory actions throughout the course of experimental colitis, and that it does so by preventing AnxA1 cleaving. A graphical representation of such findings is depicted in Figure 9.

## CONCLUSION

Data obtained in the present work evidence pioglitazone attenuates inflammation *in vivo* in a murine colitis model, and prevention of AnxA1 cleaving seems to be involved with such effect. Data obtained *in vitro* show that this process occurs in macrophages, and that pioglitazone effects rely on ERK phosphorylation, which requires AnxA1. This sum of evidence allows us to suggest that the beneficial effects of pioglitazone on the treatment of IBDs are connected to AnxA1 cleaving rather than its expression. As AnxA1 has been increasingly targeted as a potential predictor of IBD progression and treatment-induced remission, this evidence is of value for future clinical trials investigating PPAR $\gamma$  ligands for treatment of IBDs, as biomarkers which might indicate more accurately how therapeutic success on patients is more likely to be achieved, such as AnxA1, can be more thoroughly assessed.

Non-responsiveness to anti-TNF- $\alpha$  therapies presents relevant rates in inflammatory bowel disease patients, presenting the need to find biomarkers involved in therapeutic efficacy. Herein, we demonstrate that higher levels of colonic formyl peptide receptor 1 and annexin A1 correlate with histological recovery in Crohn's disease patients under remission. Using the dextran sulfate sodium colitis model in mice, we suggest that infliximab induces annexin A1 expression and secretion in activated intestinal leukocytes. Conversely, this mechanism might stimulate epithelial formyl peptide receptors, inducing wound healing and consequent histological remission. Our data indicate that assessing intestinal expressions of formyl peptide receptors and annexin A1 might provide precious information on the disease activity and responsiveness to infliximab in inflammatory bowel disease patients.

**Keywords:** biomarkers, formyl peptide receptor, annexin A1, infliximab, Crohn's disease, dextran sodium sulfate

## INTRODUCTION

Inflammatory bowel diseases (IBDs), mainly Crohn's disease (CD) and ulcerative colitis (UC), are characterized by severe gastrointestinal inflammation (1). Biological therapies, such as monoclonal antibodies and infliximab (IFX), are very effective in inducing remission for moderate-to-severe IBDs (2, 3). By binding soluble and transmembrane tumor necrosis factor alpha (TNF- $\alpha$ ), IFX attenuates inflammation and decreases the need for surgery (2, 4, 5). However, side effects and non-responsiveness illuminate the relevance of validating biomarkers to assess therapeutic efficacy (6, 7).

We previously described a possible relationship between the response to IFX and the expression of annexin A1 (AnxA1) in mice with experimental colitis (8). AnxA1 is a resolutive mediator in human and experimental conditions such as cardiovascular diseases (9, 10), multiple sclerosis (11),

and rheumatoid arthritis (12). AnxA1 is produced by epithelial cells and secreted by infiltrating leukocytes in IBD patients (13). Local expression of AnxA1 is pivotal to tissue recovery in CD and experimental colitis (14–16). Recently, it has been suggested that low levels of AnxA1 in CD support the uncontrolled inflammation that perpetuates the disease and that differential expressions of AnxA1 might allow the identification of disease severity patterns (14, 17). After cell activation, AnxA1 is mobilized to the membrane, where it is able to trigger anti-inflammatory pathways through formyl peptide receptors (FPRs) (18). FPRs have been increasingly studied in IBD as they participate in antimicrobial and inflammatory processes. FPR expression in the gut correlates with pathology during acute inflammation, but plays a protective role in the chronic phases (19). FPR1 is a wound closure mediator (20, 21), whereas FPR2 induces mucosal healing by regulating the traffic of leukocytes into the inflamed tissue (22, 23).

This background provides valuable information about the roles of AnxA1 in IBD; however, only a couple of studies—including ours—have addressed the involvement of AnxA1 in the efficacy of IFX (8, 14). Also, none has explored the potential participation of the AnxA1–FPR axis. Herein, we describe some IFX mechanisms that are affected by the AnxA1–FPR axis and seek to explain how it could mediate distinct responses to anti-TNF- $\alpha$ .

**MATERIALS AND METHODS**

**Patient Approach and Ethics Statement**

CD patients from the Santa Casa School of Medical Sciences (São Paulo, Brazil) and donors with no IBD history willingly donated blood (12 ml). Medical records and paraffinized colon biopsies provided the CD Activity Index (CAI) (24) and microscopic grading (25). This study was conducted in accordance with the Declaration of Helsinki and the ethics boards from Santa Casa and

the University of São Paulo (protocol #07100819.3.0000.0067). Written consent was obtained.

**Criteria for Patient Enrollment**

The diagnosis of CD for patients participating in this study took into account endoscopic, histological, and clinical criteria assessed and interpreted by members of the medical staff from the Santa Casa School of Medical Sciences. Individuals younger than 18 years and/or with a diagnosis of an infectious disease (such as tuberculosis, chlamydia, and the common flu) were excluded.

Participants were divided into groups as follows:

**Blood donors:** Healthy individuals with no prior history of IBD provided control samples of blood matching the average age, gender, and ethnicity from CD groups. “Remission patients” reached clinical remission upon IFX treatment, while “Failure patients” were refractory to previous therapies and were not responding clinically to IFX at the moment of blood donation. One untreated CD patient provided active disease parameters and was receiving other medications (including immunosuppressants and corticosteroids), but not IFX.

**Biopsy donors:** Remission patients reached clinical and histological remission when treated with IFX. The Failure group was composed of patients who did not present improvement of clinical parameters and histological homeostasis upon IFX. “CD untreated” individuals were those with an active disease despite treatment administration of other medications (including immunosuppressants and corticosteroids), but not IFX.

It should be noted that all patients enrolled in this study had previously received or were receiving other medication classes at the time of our sample collection. The absence/interruption of responsiveness to other therapies followed by remission or non-remission upon IFX was the defining parameter for separating the Remission and Failure groups, respectively. Clinical parameters (mean and range of age, gender, and concomitant

medications) from the Untreated CD, CD+IFX Remission, or CD+IFX Failure groups are presented in **Table 1**.

### Isolation of Leukocytes and Detection of AnxA1 in the Blood of CD Patients

Blood from healthy donors ( $n = 5$ ) and CD patients treated with IFX ( $n = 23$ ) or not ( $n = 1$ ) was used to isolate the following:

**Plasma AnxA1:** AnxA1 was detected in plasma samples using an ELISA kit (MyBioSource, San Diego, CA, USA).

**Leukocytes:**  $\text{NH}_4\text{Cl}$  (0.13 M) was added to the remaining cell fraction to lyse erythrocytes. Pellets were fixed in 1% paraformaldehyde (PFA) and incubated with anti-FPR1 (PE, R&D Systems, Minneapolis, MN, USA) and anti-FPR2 (FITC, Bioss, Woburn, MA, USA) antibodies. Readings were conducted using a BD Accuri Flow Cytometer (BD Biosciences, Franklin Lakes, NJ, USA) to acquire 10,000 events/sample. Positive populations were determined by labeling for each antibody separately.

### Detection of AnxA1, FPR1 and FPR2 in CD Biopsies

Paraffin-embedded colon biopsies from CD untreated ( $n = 4$ ) and treated positive ( $n = 3$ ) or negative ( $n = 2$ ) responders to IFX were permeabilized (0.01% Triton), retrieved (sodium citrate buffer), and blocked (20% fetal bovine serum, FBS). Samples were incubated with mouse anti-FPR1 (1:25, clone 5F1; BD Biosciences), anti-FPR2 (1:10, clone 2D8; Sigma-Aldrich, St. Louis, MO, USA), or anti-AnxA1 (1:50, clone 1B, 10  $\mu\text{g}/\text{ml}$ ). Incubation with 20% FBS provided the negative control. After incubation with anti-mouse Alexa Fluor 488 secondary antibody (1:200; Thermo Fisher, Waltham, MA, USA) and DAPI, the slides were mounted and five regions of interest (ROIs) per slide were photographed on a confocal microscope (Zeiss LSM800). Before acquiring images, the settings for gain, offset, and exposure time were adjusted based on the reaction control and standardized for each ROI from the stained samples. Acquired composite images (.czi format) were imported to Fiji (ImageJ Software, Bethesda, MD, USA) and split into blue and green channels. For densitometric analysis, the green channel (Alexa Fluor 488) was selected and modified to be displayed with a gray filter. Background pixel averages were then subtracted from the image pixels of interest to correct uneven illumination with the aid of the "Process > Math > Subtract" process. Fluorescence measures were performed manually by the selection of positive regions; average values were expressed in arbitrary units.

### Ethics Statement and Animals

C57BL6 wild-type (WT) or AnxA1-null mice ( $\text{AnxA1}^{-/-}$ ), males, 8–10 weeks old, were used to perform colitis. WT C57BL6, males, 16–18 weeks old, were used to provide intestinal immune cells to *ex vivo* experiments. Mice were obtained from the Federal University of São Paulo Animal House (Brazil), kept in 12:12-h light/dark cycle, and provided with food and water *ad libitum*. Experiments were performed in accordance with the Brazilian laws of protection and approved by the Committee on Ethics of Animal Experiments from the University of São Paulo.

### Colitis Model and Clinical Analysis

Fresh 2% dextran sodium sulfate (DSS; weight/volume, 40 kDa; Dextran Products Limited, Scarborough, Ontario, Canada) was added to the drinking water of WT and  $\text{AnxA1}^{-/-}$  mice (day 0) and replenished every other day up to day 6 (26). Control and non-treated DSS mice received vehicle (sterile saline 0.9% + DMSO 0.5%) intraperitoneally (i.p.) on days 0–9. DSS-treated groups received i.p. IFX (1 mg/kg; Remicade® Janssen-Cilag, Buenos Aires, Argentina) on day 1 and/or FPR antagonist Boc-2 (10  $\mu\text{g}/\text{kg}$  N-t-BOC-MET-LEU-PHE, MP Biomedicals, Irvine, CA, USA) on days 0–9. Body weight, diarrhea, and rectal bleeding were scored daily to provide the Disease Activity Index (DAI). On day 10, mice were euthanized by overexposure to nasal anaesthesia [isoflurane; 2-chloro-2-(difluoromethoxy)-1,1,1-trifluoro-ethane].

### Dosage of Tissue MMP-9

Samples of medium colon were homogenized in RIPA buffer containing a protease inhibitor (1:100; Thermo Fisher) in an Ultra-Turrax homogenizer (T10-Basic-IKA). After 20 min on ice, the tissue debris were removed and matrix metalloproteinase 9 (MMP-9) was detected by ELISA (R&D Systems).

### Histological Analysis *In Vivo*

Distal colons were fixed in 4% buffered PFA, dehydrated, and embedded in paraffin. Samples were analyzed using high-power objectives on the Imager.A2 Zeiss microscope (Zeiss, Oberkochen, Germany).

### Histopathology

Histological grading was based on a previous report (8). The following features were analyzed by a blinded histologist: changes on crypts and histoarchitecture, edema, ulceration and immune cells at the epithelium, lamina propria, or submucosa. Grades of 0, 1, 2, 3, and 4 were respectively attributed to normal, mild, mild-moderate, moderate-severe, and severe conditions. Results were expressed as the mean of total grading.

### Immunohistochemistry

After permeabilization (Triton 0.01%) and antigen retrieval (sodium citrate buffer, 10 mM, pH 6.0), peroxidase was inactivated with 3% hydrogen peroxide. Samples were blocked with 10% Tris-buffered saline-bovine serum albumin and incubated with the anti-AnxA1 antibody (1:500; Thermo Fisher). The reaction control was incubated with a blocking solution. The slides were finalized with an anti-rabbit horseradish peroxidase (HRP) antibody (Abcam, Cambridge, UK), 3,3-diaminobenzidine (DAB; Thermo Fisher), and hematoxylin counterstaining.

### Immunofluorescence

Permeabilized samples were retrieved in sodium citrate buffer and blocked with 20% FBS. Antibodies were incubated overnight (4°C): polyclonal mouse anti- $\beta$ -actin (1:200) and rabbit anti-villin (1:50; Abcam). After secondary antibodies (anti-mouse DyLight 549 and anti-rabbit FITC, 1:200; Vector Laboratories, Burlingame, CA, USA), the nuclei were stained with DAPI.

### Isolation of Leukocytes From Lamina Propria and Flow Cytometry

Leukocytes from proximal colonic lamina propria were isolated after washes with 2 mM EDTA and digestion with collagenase V from *Clostridium histolyticum* (1 mg/ml; Sigma-Aldrich) (26). The cells were washed through 40- $\mu$ m strainers (Corning, Corning, NY, USA) and stained with CD4 (FITC) and CD25 (APC) (1:100; BD Biosciences). Positive populations were determined by labeling with single antibodies. A minimum of 10,000 events per sample were acquired on a BD Accuri Flow Cytometer. The results were expressed as percentages of positive cells normalized by controls from each experiment.

### Isolation of Colonic Lamina Propria Leukocytes and Ex Vivo Treatments

After euthanasia by overexposure to isoflurane, colons from C57BL6 mice were opened longitudinally and washed with supplemented phosphate-buffered saline (10,000  $\mu$ g/ml penicillin/streptomycin and 50  $\mu$ g/ml gentamycin). Under a sterile hood, the tissues were fragmented, washed in Hank's salt solution buffer without calcium/magnesium for 20 min (twice), and digested with collagenases from *C. histolyticum* (types II and IV, 0.5 mg/ml; Gibco, Waltham, MA, USA). The digested tissue was washed twice through 40- $\mu$ m strainers (Corning) and the pellets were counted and resuspended at the Roswell Park Memorial Institute (RPMI + 1% FBS). Cells were seeded in a 96-well plate ( $2 \times 10^5$ /well) and treated with 200 ng/ml lipopolysaccharide (LPS; Sigma-Aldrich) 30 min before IFX (0.1, 1.0, or 10.0  $\mu$ g/ml). Controls were untreated or treated with those IFX doses. After 24 h, the supernatants were collected to dose secreted AnxA1 (MyBioSource) according to the manufacturer's instructions.

### Statistical Analysis

To determine the parametric or non-parametric distributions, we used the Kolmogorov-Smirnov test. ANOVA followed by Tukey's was performed for parametric tests, and Kruskal-Wallis followed by Dunn's post-test was performed for non-parametric tests. To compare the two groups, we applied unpaired (single measures) or paired *t*-test (repeated measures). Pearson's correlation was performed for correlation analysis, providing the correlation coefficient *r* and the coefficient of determination  $R^2$ . Probabilities with  $p < 0.05$  were considered significant. The results were expressed as the mean  $\pm$  standard deviation (SD; human samples, individual variabilities) or standard error of the mean (SEM; *in vivo/ex vivo* assays, group variability). All statistical assessments were conducted using GraphPad Prism<sup>®</sup> software, version 9.1.2 (San Diego, CA, USA).

## RESULTS

### AnxA1 and FPR1 Are Differentially Expressed in the Colon of CD Patients Responsive to IFX

Recently, it has been suggested that differential expressions of AnxA1 might allow the identification of disease severity patterns

in IBD (14, 17). Thus, we proposed screening the expression patterns of AnxA1 and its receptors, FPR1 and FPR2, in CD biopsies of colons from untreated and IFX-treated patients who either went into remission or did not. Information about the healthy volunteers and CD patients are listed in Table 1.

Hematoxylin/eosin-stained colon biopsies revealed ulcers, crypt alterations/abscesses, and prominent inflammatory infiltrates in untreated and IFX Failure patients (Supplementary Figures 1A, C). Based on the grading system (Supplementary Table 1), we confirmed lower histological damage for remittent (Supplementary Figure 1B and Figure 1F) rather than untreated CD individuals.

Subsequently, FPR1, FPR2, and AnxA1 were detected on the colon biopsies using confocal microscopy (Figure 1). For those three markers, the Z-scores were above the population mean for the IFX-induced remission group, contrasting with the lower levels in the untreated and IFX Failure groups (Figure 1A). Despite the increased fluorescence detected for FPR1 (Figures 1C, G) and FPR2 (Figures 1D, H) in remittent patients, only AnxA1 was significantly higher than that in the untreated group (Figures 1E, I). Epithelial cells from barrier, crypts, and leukocytes were the major sources of FPR1, FPR2, and AnxA1. Furthermore, colonic FPR1 and AnxA1 expressions presented a strong negative correlation with the histological grading (Figures 1J, L), which means that the decrease of these markers is associated with more tissue damage. For FPR2, a moderate correlation was detected ( $r = -0.5355$ ), but this was not enough to characterize a significant association (Figure 1K). Based on this, we presume that the upregulation of colonic FPR1 and AnxA1 in CD positive responders to IFX provides a marker of differential expression for therapy efficacy.

Using the patients' medical histories, we calculated the CDAI (Supplementary Table 2). Despite the different intensities of disease activity among patients, no patterns for circulating FPR1, FPR2 (leukocytes), or AnxA1 (plasma) were observed for the healthy, remission, or failure groups (Supplementary Figure 2A). As expected, CDAI was significantly higher in IFX-unresponsive patients than in remission patients (Supplementary Figure 2B). Furthermore, FPR1, FPR2, and AnxA1 in blood did not correlate with CDAI, indicating that patients' circulating levels might not be reliable biomarkers for remission or failure after IFX treatment (Supplementary Figures 2C-H).

### FPR Signaling Complements the Beneficial Effects of IFX on Colitis Symptomatology and Tissue Damage

After detecting the correlations between high expressions of FPR1/AnxA1 and histological recovery in CD, we wondered how the modulation of these markers would impact resolution after IFX. We have previously demonstrated the failure of IFX in treating acute colitis using AnxA1-null Balb/c mice (8). To explore the mechanisms involved in the efficacy of IFX, we performed DSS-induced colitis in WT and AnxA1<sup>-/-</sup> C57BL6 mice and followed up to the late phase of the disease (Figure 2 and Supplementary Figures 3, 4). As expected, colitis induced significant weight loss and increased the DAI in both WT (Figures 2A-C) and AnxA1<sup>-/-</sup> strains (Supplementary

**Figures 4A, B.** Anatomic and microscopic alterations were also produced by DSS, including colon shortening, MMP-9 increase, ulcers, altered crypt, crypt abscesses, vacuolar hydropic degeneration, submucosal edema, and mucosal/submucosal

massive inflammatory infiltrates (**Figures 2D–H** and **Supplementary Figures 4E–I**). IFX attenuated body weight loss (days 9 and 10; **Figure 2A**) and DAI during the late phase of the disease (day 8; **Figures 2B, C**) in WT mice. Except for

some remaining infiltrated leukocytes and submucosal edema, the colonic histological architecture was protected by IFX (Figure 2J). These improvements were not only absent in the *AnxA1*<sup>-/-</sup> group upon IFX treatment (Supplementary Figures 4A, B, J), but anti-TNF- $\alpha$  seemed to be harmful without endogenous *AnxA1* as well: a 50% mortality rate was recorded (Supplementary Figure 4C). *AnxA1*-deficient mice had significant colon shortening (Supplementary Figures 4E, F) and a 200- to 300-fold increase in tissue MMP-9 with or without IFX treatment (Supplementary Figure 4G). Moreover, *AnxA1*<sup>-/-</sup>/DSS+IFX mice had less intestinal T regulatory lymphocytes than did the mice in the respective WT group and the untreated group (*AnxA1*<sup>-/-</sup>/DSS), reaffirming the relevance of *AnxA1* to the downregulation of inflammation even when TNF- $\alpha$  is being blocked by IFX (Supplementary Figure 4D).

For the next step, we blocked the *AnxA1* receptors, FPRs, to assess their potential involvement in the effects of IFX. The FPR blockade, by itself, confirmed their well-known role in wound healing (15, 27). FPR neutralization was detrimental to the clinical parameters in both early and late phases of disease (Figures 2A-C), intensified colon shortening (Figures 2D, E), and increased MMP-9 (Figure 2F). Microscopically, the FPR blockade with Boc-2 worsened the DSS damage, especially with regard to epithelial/glandular loss and infiltrated leukocytes

(Figure 2I). When combined with IFX, blocking FPRs was detrimental to the clinical conditions in the late phase as the beneficial effects of IFX on body weight and DAI were lost (days 9 and 10 and day 8 in Figures 2A, B, respectively) (Figure 2C). Although the colon length and MMP-9 from IFX-treated mice were not affected by Boc-2 (Figures 2D, E), the cecum very consistently assumed a distorted morphology and paleness for this group (Figure 2D).

Finally, the histological parameters were analyzed. IFX-mediated preservation of the colonic histoarchitecture was partially impaired by an FPR blockade, with the presence of immune cells in the mucosa and punctual but persistent ulcerations (Figure 2K). The clearest histological alteration in this group was poor crypt recovery (details in Figure 2K). For this reason, we proceeded to explore the effects of halting the signaling through FPRs for the regeneration of crypts after IFX treatment.

### Blocking FPRs Compromises the Effects of IFX on Crypt Regeneration

The relevance of FPRs for crypt regeneration was confirmed by structural protein immunostaining (Figure 3). In control mice,  $\beta$ -actin revealed the cylindrical shape of enterocytes (Figure 3A, a1) with villin expressed on the apical surfaces of cells (Figure 3A, a2). A similar pattern was observed on crypts

from DSS+IFX mice (Figure 3B, b1 and b2). In both groups, it is possible to identify the secretory and excretory portions from the mucosal glands, forming a U-shaped structure with a centered vertical lumen that opens to the intestinal wall, where the secretions produced by crypts are liberated.

Upon FPR inactivation, with or without IFX treatment, crypt cells assumed a deformed morphology lacking cylindrical limits. The elongated shape from crypts gave place to an amorphous structure, many times with the lumen turned into a round form that was no longer connected with the epithelium surface (Figure 3C, c1). In this space, we observed residues of the shed villin (Figure 3C, c2 and c3, green) that co-localized with DNA (Figure 3C, c2 and c3, blue). FPRs were associated with epithelial repair, migration, and wound healing before, but our results

suggest that these roles are also required for the intestinal barrier homeostasis mediated by IFX. Considering that AnxA1 is an important FPR agonist and a pivotal mediator of tissue repair in IBD, our final step was to assess the possible kinds of interplay among AnxA1 expression, FPR activation, and IFX efficacy.

### IFX Induces AnxA1 Expression and Secretion by Tissue Leukocytes During Inflammation

Intracellular and FPR-binding AnxA1 mediate inflammation resolution and tissue repair on experimental colitis (8, 28). In our model, we assessed the expression patterns for endogenous AnxA1 in the colon (Figure 4). The reaction control confirmed specificity (Figure 4).

In the control epithelium, AnxA1 was weakly detected (Figure 4A). Colitis upregulated AnxA1 in the damaged epithelium from the DSS and DSS+Boc-2 groups (Figures 4B, D). Mice treated with IFX, with or without FPR signaling, presented epithelial AnxA1 similar to the control group (Figures 4C, E). In turn, AnxA1 was weakly detected in tissue leukocytes in non-treated colitis (Figure 4F). After IFX, a high number of infiltrated AnxA1-positive immune cells were observed (Figure 4G). AnxA1 was also detected in leukocytes under Boc-2 (Figure 4H). Interestingly, in mice treated with IFX and Boc-2, most tissue leukocytes were negative for AnxA1 (Figure 4I).

Because the intracellular expression of AnxA1 was upregulated in tissue leukocytes upon IFX, we hypothesized that transmigrated immune cells could be important sources of AnxA1 for the inflamed tissue treated with this anti-TNF-α. Using LPS *in vitro* assays, we simulated an inflammatory response in immune cells isolated from the colon of naive mice. When treated with increasing concentrations of IFX (0.1, 1.0, and 10 μg/ml), we detected a dose-dependent augmentation in AnxA1 secretion to the milieu (Figure 4K). This phenomenon

was reproduced in the DSS-induced colitis treated with IFX, as colon explant supernatants had increased levels of AnxA1 compared to the control group (Figure 4L). Finally, we observed a moderate negative correlation between the secreted AnxA1 and the grading for histological damage of the colon (Figure 4M). These results suggest that IFX induces AnxA1 expression and secretion by tissue leukocytes, and this mechanism is linked to tissue repair.

**DISCUSSION**

Previously, we reported the relevance of AnxA1 in the efficacy of IFX during acute colitis in female Balb/c mice (8). Here, we corroborate it using mice of different strain and sex and focusing on the late phase of disease. On biopsies from CD patients, we further confirm that IFX modulates AnxA1 in positive responders. Moreover, we describe FPR1 as a potential marker of tissue homeostasis after IFX treatment. Our results suggest that IFX stimulates activated intestinal leukocytes to express and

secrete AnxA1 to the inflamed milieu, where it is free to bind to FPRs and promote tissue repair (29).

Although biologicals are the most successful drug class at inducing remission among the therapies classically used to treat IBD (30), they still burden patients with heterogeneous outcomes, including hypersensitivity, allergies, lack of responsiveness, or progressive loss of efficacy over the lifetime (31). Even clinically remittent patients may present remaining mucosal inflammation associated with severe mucosal disease activity (32). In response to this, the follow-up protocol for treated patients proposes the assessment of histological remission as a more reliable tool to predict a sustained and steroid-free clinical remission, with lower need for hospitalization and surgery (33). Herein, we observed a marked expression of AnxA1 in the colon of CD patients who underwent remission after IFX. For AnxA1 and FPR1, high tissue levels correlated with lower histological damage. In a general manner, the literature on IBD suggests that AnxA1 secretion is evoked during the active disease. Failures in this mechanism contribute to a more severe and prolonged disease (26, 34). Similarly, therapeutic interventions have a better outcome when capable of increasing AnxA1 levels (8, 14). In the inflamed site, AnxA1 binding to FPRs mediates the resolution of inflammation and mucosal homeostasis (16, 28). The data we present here support the mechanisms described above. Moreover, they suggest that tissue FPR1 and AnxA1 could constitute useful tools for following up the disease activity and the efficacy of IFX in CD patients.

Mucosal inflammation begins with the opening of the epithelial barrier after injury, which allows the translocation of microbial agents. Once the commensal microbiota is detected by the immune cells that patrol the tissue, an inflammatory response is assembled to contain the spreading of bacteria to the blood and other tissues. However, an unbalanced inflammation feed-forwards tissue damage and increases bacterial translocation (35). Upon injury or death, column-shaped intestinal epithelial cells can lose contact with each other, assuming a flat morphology. The organism responds by triggering a proliferation of basal crypt cells and epithelial migration, promoting wound closure (36). By binding FPRs, full-length AnxA1 and its peptide, Ac2-26, stimulate the migration of epithelial cells and wound healing (15, 16). Ac2-26 binding to FPR1 induces oxidative inactivation of phosphatase and tensin homolog protein and protein tyrosine phosphatase-PEST, phosphorylating focal adhesion kinase and paxillin, consequently stimulating cells to migrate (15). Additionally, endogenous AnxA1 acts as an anchor between cytoplasmic  $\beta$ -actin and the plasma membrane, whereas the AnxA1-FPR2 axis inhibits RhoA GTPase activity, stabilizing the cytoskeleton (37). Our results confirmed that the lack of endogenous AnxA1 is very detrimental to the progression of experimental colitis: AnxA1<sup>-/-</sup> mice had much worse clinical and histological outcomes, fewer intestinal regulatory T cell (Treg) counts, and a 25% mortality rate compared to WT mice. Preventing AnxA1 and other agonists from binding with FPRs *in vivo* was almost equally harmful as all clinical

parameters were impaired and tissue damage was remarkable, especially considering crypt and epithelial loss. Interestingly, treatment with IFX did not compensate for the absence of endogenous AnxA1 or FPR signaling. The blockade of the AnxA1-FPR axis impaired crypt restitution, whereas a lack of AnxA1 impacted the ability of IFX to promote wound healing and to rebalance the immune response. Based on these data, we propose that protection of the epithelial barrier with IFX must be complemented by the downstream pathways resulting from the binding of AnxA1 (and other endogenous agonists) to FPRs (Figure 5).

It is well known that the use of IFX on chronic diseases modulates cellular pathways downstream of TNF receptors (TNFRs) by blocking soluble and transmembrane TNF- $\alpha$  (38, 39). Considering the complexity of the mechanisms evoked by IFX and the heterogeneous responses it produces, other endogenous players are likely to be involved in successful outcomes. Herein, we suggest that AnxA1 expression might be one mechanism induced by IFX, which may, in turn, regulate its effects at some level. This notion is supported by the modulation of intracellular and secreted AnxA1 after IFX treatment in colitic mice. In colonic mucosal and submucosal leukocytes activated by inflammatory mediators, IFX evoked AnxA1 expression. The same group had increased secretion of AnxA1, which was most likely being provided by those leukocytes. In line with this, increased levels of AnxA1 were secreted as higher doses of IFX were added to LPS-stimulated intestinal leukocytes *ex vivo*. These results seem to be translatable to the human condition because we also observed increased AnxA1 in biopsies from CD patients in association with histological remission. Indeed, the lack of TNF- $\alpha$  signaling through TNFR1 in mice during colitis favors tissue AnxA1 expression and increases the frequency of CD4<sup>+</sup> and CD8<sup>+</sup> T lymphocytes positive for AnxA1 (26). These data indicate that intestinal immune cells are the major sources of secreted AnxA1; this could be one resolutive mechanism of IFX that was not previously described. Interestingly, the Boc-2 groups had less secreted AnxA1 with or without IFX. This suggests a more complex mechanism of action for IFX, in which proper FPR signaling is required to induce AnxA1 secretion by leukocytes and, in turn, to mediate tissue repair and wound healing.

Obviously, FPR agonists other than AnxA1 could be involved in the efficacy of IFX. In the inflammatory milieu, FPR ligands can be found among endogenous metabolites, peptides, and damage- and pathogen-associated molecular patterns (DAMPs and PAMPs, respectively) (40). These include *N*-formyl-peptides from mitochondrial damage (41), the antimicrobial peptide LL-37 and lipoxin A4 (22). It should be noted that the bacterial-derived peptide formyl-methyl-leucine-phenylalanine (fMLP) can be present at high concentrations in the wounded intestinal tissue (42) and binds FPR1 with a strong affinity, triggering healing pathways on epithelial cells (20, 43). Despite that, this work addresses AnxA1 participation because of its pivotal roles in IBD. Our choice was also supported by the increased AnxA1 secretion upon IFX in experimental colitis and its correlation with tissue recovery. It is also important to point out that, although we argue that AnxA1 and FPRs contribute to

the efficacy of IFX, it is possible that they might be involved in the effects of other therapies as well. We do not claim that this modulation is exclusive to IFX, but that it obtains for this specific therapy. We hope that our study encourages others to explore therapies that might be complemented by AnxA1-FPR, elucidating possible mechanisms of therapeutic failure in IBD. We believe that the data we presented here may contribute to the identification of poor responsiveness cases, leading to long-term remission based on the pivotal homeostatic roles of AnxA1 through FPRs.

### ABSTRACT

Annexin A1 (AnxA1), a 37kDa protein, is secreted by inflammatory and epithelial cells and displays anti-inflammatory and wound healing activities in intestinal bowel diseases. Herein, we aimed to functionalize recombinant AnxA1 (AnxA1) on multi-wall lipid core nanocapsules (MLNC) and investigate its effectiveness on experimental colitis. MLNC were prepared by covering lipid core nanocapsules (LNC) with chitosan, which coordinates metals to specific protein chemisorption sites. Therefore, MLNC were linked to Zn<sup>2+</sup> and AnxA1 was added to form MLNC-AnxA1. LNC, MLNC and MLNC-AnxA1 presented average size of 129, 152 and 163 nm, respectively, and similar polydispersity indexes (0.xx); incorporation of chitosan inverted the negative potential zeta; the coordination efficiency of AnxA1 was 92.22 %, and transmission electron microscope photomicrograph showed MLNC-AnxA1 had a spherical shape. The effectiveness of MLNC-AnxA1 was measured in Dextran Sulfate Sodium (DSS)-induced colitis in male C57BL/6 mice. DSS (2 % solution) was administered from days 1–6; saline, LNC, MLNC, MLNC-AnxA1 or AnxA1 were administered, once a day, by oral or intraperitoneal (i.p.) routes, from days 6–9. Clinical parameters of the disease were measured from day 0–10 and gut tissues were collected for histopathology, immunohistochemistry and flow cytometry analyses. Only i.p. treatment with MLNC-AnxA1 reduced weight loss, diarrhea and disease activity index, and prevented loss of colonic structure integrity; induced the switch of macrophages into M2 phenotype in the lamina propria; recovered the colonic histology architecture by decreasing dysplasia of crypts, inflammation and ulcerations; restored the expression of claudin-1 Zonula-occludens-1 tight junctions in the inflamed gut; and induced stem cell proliferation in intestinal crypts. Associated, data highlight the functionalization of MLNC with AnxA1 as a tool to improve the local actions of such protein in the inflamed gut by inducing resolution of inflammation and tissue repair.

### 1. Introduction

Inflammatory bowel diseases (IBDs) are chronic and multifactorial disorders characterized by an exacerbated and progressive immune response to homeostasis disruption of the intestinal epithelium [1]. IBDs comprise Crohn's disease (CD) and ulcerative colitis (UC) [2]. Lesions spread out at different parts of the intestine characterize CD, leading to

inflammation at the transmural level [3]. UC, on the other hand, is typically limited to the colon, affecting the mucosal and submucosal layers [4–5]. The exact etiology of IBDs remains unclear; however, genetic variations in the immune system, alterations in the intestinal microbiota, and exposure to environmental pollutants are strongly associated with induction and development of IBDs [6]. Current pharmacotherapy on IBDs treats only symptoms of the disease all the while

being highly costly. Furthermore, patients may be unresponsive to available treatments. Hence, novel therapies for IBDs treatment are being constantly researched [7].

Inflammation is mediated by a diversity of pro-inflammatory mediators secreted in order to evoke an effective response against an aggressor. Nevertheless, such process cannot be exacerbated otherwise risking injuring host tissue, and for this reason anti-inflammatory mediators are secreted to halt and resolve the process. Annexin A1 (AnxA1) is a 37 kDa protein secreted by immune and epithelial cells, known as a blocker of neutrophil recruitment into lesioned areas and as an inducer of efferocytosis and tissue repair [8–9]. AnxA1 anti-inflammatory actions occur due to binding to formyl-peptide receptors (FPRs) in cell membranes, and subsequent activation of downstream intracellular pathways [8,10–11].

Data obtained from samples collected from IBDs patients or experimental models of colitis show AnxA1 is highly expressed by epithelial and inflammatory cells during IBDs course, being associated with the protection of gastrointestinal mucosa and epithelial recovery by activating FPR1 and FPR2 [12–18]. AnxA1 has been claimed as a marker of IBD [14,18–19]. It was recently shown that AnxA1 mediates the actions of therapeutic drugs on treatment of IBD, such as infliximab, an anti-tumor necrosis factor (anti-TNF) antibody [19], and pioglitazone, an ligand of the peroxisome proliferator-activated receptor  $\gamma$  [13].

Lipid core nanocapsules (LNC) are biodegradable and efficiently load poorly water soluble molecules [20]. LNC enhance bioavailability and drive different lipophilic molecules to pharmacological targets, being capable of crossing biological barriers including the gastrointestinal and the blood-brain-barrier. Therefore, drug-loaded LNC represent potential formulations to treat inflammatory and cancer diseases [21–28]. More

recently, LNC technology was improved to allow carrying of polar molecules, as proteins, enzymes and antibodies due to the development of multi-wall lipid core nanocapsules (MLNC) [29]. MLNC are built by adding chitosan-metal complexes in order to adsorb molecules containing heteroatoms in their chemical structure, including oxygen or nitrogen. The metal complex with Zn<sup>2+</sup> provides better binding of proteins to the MLNC structure by interacting with histidine residues present in the C-terminal region of molecules [30]. Recent studies have demonstrated the higher bioavailability and therapeutic effectiveness of MLNC functionalized with hydrophilic molecules, including enzymes and proteins [31–33].

Considering the feasibility of MLNC to load proteins, we here developed MLNC functionalized with recombinant AnxA1 (AnxA1) and tested its effectiveness on experimental model of colitis in mice.

## 2. Material and methods

### 2.1. Materials

Protease inhibitor cocktail, poly( $\epsilon$ -caprolactone) ( $\alpha,\omega$ -dihydroxy telechelic PCL, Mw = 14,000 g mol<sup>-1</sup>), sorbitan monostearate (SM, Span 60®), polysorbate 80 (Tween 80®), zinc acetate, low molecular weight chitosan (Mw = 50,000–190,000 g mol<sup>-1</sup>, deacetylation degree: 75–85 %, viscosity: 20,000 cP) (Sigma-Aldrich Co, Saint Louis, MO, USA); soybean phosphatidylcholine (LPS75; 75 % pure; Lipoid® S75, Gerbrás Quimica Farmacêutica Ltda, São Paulo, Brazil); medium chain triglyceride (MCT, Nutrimed Ind. Ltda, São Paulo, Brazil). Recombinant AnxA1 (AnxA1) protein was purified by a previously established method [34] and provided by Professor Chris Reutelingsperger, from Maastricht University; acetone and ethanol used were of analytical grade; dextran sulfate sodium (DSS, MW 40,000, Dextran Products Limited, Canada); anti-mouse CD206 and anti-mouse Zonula occludens-1 (ZO-1; Invitrogen®, Waltham, Massachusetts, USA); anti-mouse F4/80, anti-mouse CD80 (eBioscience™, San Diego, California, USA); anti-mouse Claudin-1 and secondary antibody anti-rabbit conjugated with HRP (Abcam Plc, Cambridge, United Kingdom); anti-mouse Ly6G (BD, Becton Dickinson, New Jersey, US); DAB Substrate Chromogen System (Dako Omnis, Agilent, Santa Clara, California, USA); anti-Ki67 (Cell Signaling Technologies, Danvers, Massachusetts, USA); anti-proliferating cell nuclear antigen (PCNA), Santa Cruz Biotechnology, Dallas, Texas, USA); Collagenase II and Collagenase IV from *Clostridium histolyticum* and bovine serum albumin (BSA) (Gibco™, Grand Island, New York, USA). Isoflurano (Critália Produto Químicos e Farmacêuticos Ltda, São Paulo, Brazil). Paraformaldehyde, xilene, sodium citrate, peroxide and tris (hydroxymethyl) aminomethane (Synth® - Labsynth Produtos para Laboratórios LTDA, São Paulo, Brazil).

## 2.2. Synthesis of the AnxA1-Surface-Functionalised Metal-Complex MLNC

The first step of the synthesis of nanocapsules consisted of the interfacial deposition of pre-formed polymer method, as previously described [21,29]. An organic solution was prepared by addition of PCL (0.100 g), SM (0.040 g), and MCT (120  $\mu\text{L}$ ) dissolved in acetone (25 mL). An additional organic solution was prepared by mixing 5 mL of ethanol with LPS75 (0.090 g). The organic solutions were maintained under magnetic stirring at 40  $^{\circ}\text{C}$  for 1 h. Afterwards, both solutions were mixed and maintained under agitation at 40  $^{\circ}\text{C}$  for 1 h. Another aqueous solution was prepared using distilled water (60 mL) with 0.080 g of nonionic surfactant Tween® 80, by mixing for 1 h at 40  $^{\circ}\text{C}$ . Afterwards, the final organic solution was injected into the aqueous solution and stirred for 10 min. The resulting translucent solution was evaporated to

be concentrated to final volume of 9 mL, using a rotary evaporator under reduced pressure at 40  $^{\circ}\text{C}$ . The formulation consisted of lipid-core nanocapsules in aqueous dispersion (LNC). The volume of the final solution was adjusted to 10 mL using ultrapure water. The supramolecular structure is stabilized by weak forces (dipole-dipole and ion-dipole interactions).

Twenty-four hs later, 500  $\mu\text{L}$  of a filtered (0.45  $\mu\text{m}$ , Millipore, Merck Millipore, Darmstadt, Germany) aqueous solution of chitosan (0.3%) was pipetted (1 drop every 10 s) into 4.5 mL of LNC solution. The mixture was maintained under magnetic stirring for 2 hs (second step of reaction consisting of interfacial ionic bonds). Next, a  $\text{Zn}^{2+}$  solution containing 28  $\mu\text{g}$  of zinc acetate in ultrapure water (10 mL) was prepared. Thereafter, the third and fourth steps lead to the organometallic coordination, 12.5  $\mu\text{L}$  of zinc acetate solution were added into 412.5  $\mu\text{L}$  of the chitosan-coated lipid-core nanocapsules solution (MLNC) under

Fig. 3. MLNC-AnxA1 up-regulate M2 macrophage polarization in lamina propria. Cells were dissociated by enzymatic activity from extracellular matrix and  $2 \times 10^5$  cells were used for antibody labeling. (A) Ly6G<sup>+</sup>, (B) F4/80<sup>+</sup>, (C) F4/80<sup>+</sup>CD80<sup>+</sup>, (D) F4/80<sup>+</sup>CD206<sup>+</sup>,  $n = 6$  mice/group. \*  $p < 0.05$ , \*\*  $p < 0.01$  vs DSS. #  $p < 0.05$ , ##  $p < 0.01$  vs Naive.

magnetic stirring at 350 rpm. After 40 s, 75  $\mu$ L of AnxA1 solution 1.33 mg mL<sup>-1</sup> were added into the same solution under magnetic stirring at 350 rpm. The AnxA1-Zn<sup>2+</sup>-chitosan-coated lipid-core nanocapsules complex (MLNC-AnxA1) was maintained under magnetic stirring (350 rpm) for 20 min at room temperature (20 °C). At final formulation, the theoretical concentration of AnxA1 was 200  $\mu$ g mL<sup>-1</sup>. The four steps to obtain the intermediate formulations (LNC and MLNC) and the final formulation (MLNC-AnxA1) are represented in the Figure S1.

### 2.3. Physicochemical characterization of the nanocapsules

Initially, z-average hydrodynamic diameter and polydispersity index (PDI) values were calculated after determining the particle size distribution using dynamic light scattering at 25 °C (DLS; Zetasizer Nano ZS, Malvern Instruments, Malvern, UK). The measurement was performed after dilution of samples (500  $\times$ ) in purified and previously filtered water (MilliQ®) (0.45  $\mu$ m, Millipore®, Billerica, MA, USA). Zeta potential ( $\zeta$  – mV) mean values were calculated using the electrophoretic mobility distribution (Zetasizer Nano ZS, Malvern Instruments, Malvern) in formulation diluted (500  $\times$ ) in a pre-filtered (0.45  $\mu$ m, Millipore®, Billerica, MA, USA) NaCl aqueous solution (10 mM). The

quantifications of pH were carried out in the formulation using a calibrated potentiometer (DM-22, Digimed, São Paulo, Brazil). The concentration and size distribution quantification of the formulations (particle number density) were obtained by using nanocapsule tracking analysis (NTA) (NanoSight LM10 & NTA 2.0 Analytical Software, NanoSight® Ltd). Quantification of AnxA1 bound to the nanocapsules was realized by an indirect method. The free AnxA1 in the formulations was quantified by a colorimetric method (QuantiPro™ BCA Assay Kit, Sigma-Aldrich, St. Louis, MO, USA) according to manufacturer's instructions. To separate the free fraction of AnxA1, the MLNC-AnxA1 formulation was centrifugated in ultrafiltration units (100 kDa; Merck KGaA), using 1,840 xg for 5 min (Sigma® 1–14; SIGMA Laborzentrifugen GmbH, Germany). The obtained ultrafiltrate was quantified by colorimetric methods and the protein concentration was obtained using a calibration curve. The results were expressed in coordination efficiency. The morphology of the MLNC-AnxA1 formulation was visualized under a transmission electron microscope operating at 80 kV. Samples of nanocapsule (100  $\mu$ L) were diluted in water (1:10, v/v). Only 10  $\mu$ L of the diluted solution were deposited on copper grids (400 mesh), which were coated with carbon films. Afterwards, 2 % uranyl acetate solution, used as negative contrast, was added to the grid, and was kept in a

vacuum desiccator for 24 h.

#### 2.4. Animals

Male C57BL/6 wild-type (WT) mice, aged 8–10 weeks and weighting 20–25 g were used. Animals, obtained from Faculty of Pharmaceutical Sciences of the University of São Paulo. They were maintained under pathogen-free conditions and in a 12-h light/dark cycle, at temperatures between 20 and 25 °C, with free access to water and food. The protocol of study was approved by the Ethics Committee of Animal Use of the Faculty of Pharmaceutical Sciences of the University of São Paulo (CEUA/FCF/ USP; protocol n° 598), following the Brazilian laws of animal ethics.

#### 2.5. Colitis induction and treatments

Five groups of animals were employed ( $n = 6$  animals/group), as follow: Naive, DSS, AnxA1, MLNC and MLNC-AnxA1. The naive group received just filtered water, colitic animals (DSS, AnxA1, MLNC and MLNC-AnxA1) received DSS solution (2%) from day 1 to the day 6; the DSS solution was replaced with two days of intervals. On day 6, DSS was withdrawn and replaced with filtered water until day 10. Between days

6 and 9, the mice were treated once daily with different doses of AnxA1, MLNC, MLNC-AnxA1 or diluent solution (H<sub>2</sub>O MilliQ®) according to the route of administration. Oral: AnxA1 (100  $\mu\text{g}/\text{mL}$ ) or MLNC-AnxA1 (100  $\mu\text{g}/\text{mL} - 3.1 \times 10^{12}$  particle/ $\text{mL}^{-1}$ ); intraperitoneal (i.p.): AnxA1 (12.5  $\mu\text{g}/\text{mL}$ ), MLNC (9.6  $\times 10^{11}$  particle/ $\text{mL}^{-1}$ ) or MLNC-AnxA1 (12.5  $\mu\text{g}/\text{mL} - 9.6 \times 10^{11}$  particles/ $\text{mL}^{-1}$ ) in a final volume of 200  $\mu\text{L}$ . Naive or DSS groups were manipulated as the other groups, but with the carrier solution H<sub>2</sub>O only (MilliQ®).

Clinical parameters were achieved by measuring body weight, diarrhea and rectal blood. They were observed and registered daily and used to calculate the Disease Activity Index (DAI), as DAI was obtained by the sum of these parameters. On day 10, animals were anaesthetized by inhalation of isoflurane anesthetic (2-chloro-2- (difluoromethoxy)- 1,1,1-trifluoroethane) and euthanized. Samples of the colon were collected from the ileocecal junction up to the proximity of the anus, to macroscopic evaluation. Furthermore, fragments of the colon were used to histological (distal colon), enzymatic and flow cytometry (mid/proximal colon) analyzes. Peritoneal lavage was collected using ice-cold PBS solution and cellularity was quantified by flow cytometry.

Fig. 5. Effects of MLNC-AnxA1 treatment on epithelial tight junctions in the colon damaged by DSS-induced colitis. First line sections represent ZO-1 expression and second line sections represent Claudin-1 expression in colonic tissue. (A and F) Naive group; (B and G) DSS group; (C and H) AnxA1 group; (D and I) MLNC group; (E and J) MLNC-AnxA1 group. The quantification of ZO-1 stained area (K) and Claudin-1 (L) are presented in the graphs. (M) Control section.  $n = 6$  mice/group. Pictures: high-power objective (40 $\times$ ). Sections: 4  $\mu$ m. Scale bar: 100  $\mu$ m. \*  $p < 0.05$ , \*\*  $p < 0.01$  vs DSS. &  $p < 0.05$ , &&  $p < 0.01$  vs MLNC. #  $p < 0.05$ , ##  $p < 0.01$  vs Naive. Abbreviations: ZO-1, zonula occludens-1; DSS, dimethyl sulfoxide.

## 2.6. Histopathological and immunohistochemistry analysis

Fragments collected from the distal part of the colon were fixed by 24 h incubation in 4 % paraformaldehyde for 24 h. Afterwards, they were dehydrated in graded ethanol, cleared in xylene and embedded in paraffin for histopathological and immunohistochemistry analyses according to our previous manuscripts [13–14].

Histopathological analysis was performed in 4  $\mu$ m sections. Samples were stained using hematoxylin and eosin solution and analyzed using a high-power objective (40 $\times$ ) on an AxioCam coupled to a Zeiss microscope (Carl Zeiss, Jena, Germany). The histopathological score analysis was performed blindly by two analysts knowledgeable on characteristics of intestinal tissue. The score was adapted [35] and considered: tissue edema, dysplasia/altered histoarchitecture, crypt edema, inflammatory infiltrates and ulcerations. Ten photos were taken of each histological section using a 20 $\times$  high power objective and scores were evaluated on a scale ranging from 0 to 4.

During immunohistochemistry measurements, colon sections was achieved were deparaffinized, hydrated and incubated with sodium citrate buffer (pH 6.0) at 96  $^{\circ}$ C for 30 min. Endogenous peroxidase activity was blocked with 3 % hydrogen peroxide, three times washed after each in 10 min of incubation. Next, blocking of unspecific binding sites was carried out with 1 % BSA diluted in Tris-buffer saline (TBS) for one h. Sections obtained were incubated with anti-Claudin-1, anti-ZO-1, anti-PCNA and anti-Ki67 antibodies overnight at 4  $^{\circ}$ C. Afterwards they were washed and incubated with a secondary antibody conjugated with HRP (1 h, room temperature), and detected using 3,3'-diaminobenzidine. Finally, sections were counterstained with hematoxylin and mounted. The sections were photographed using a 20 $\times$  high power objective and the percentage of marked area of claudin-1 and ZO-1 was

quantified using ImageJ software. Results were expressed as mean  $\pm$  S.E.M. of percentage of marked area.

The quantification of proliferative nuclei was evaluated by the photographs using a 40 $\times$  high power objective in ten fields of the mucosal layer from PCNA-stained and Ki67-stained sections and the number of positive nuclei was quantified for each field assessed. Results were expressed as mean  $\pm$  S.E.M. of proliferative nuclei.

## 2.7. Isolation of Leukocytes from lamina propria and flow cytometry

Leukocytes from proximal colonic lamina propria were isolated after washes with 2 mM EDTA followed by digestion with collagenase II and IV from *Clostridium histolyticum* (1 mg/mL). The cells were washed through 40- $\mu$ m strainers (Corning, Corning, NY, USA) and stained with Ly6G (PE), F4/80 (PerCpCy5.5), CD206 (FITC) and CD80 (PE). Positive populations were determined by labeling with single antibodies. A minimum of 10,000 events per sample was acquired on a BD Accuri C6 Flow Cytometer (BD, Becton Dickinson, New Jersey, US). The results were expressed as percentages of positive cells normalized by controls from each experiment.

## 2.8. Statistical analysis

Clinical parameters in experimental colitis were analyzed by Two-way ANOVA followed by Bonferroni post-test. For other analyses, One-way ANOVA was used followed by Tukey's post-test. Values of  $p < 0.05$  were considered significant. Results were expressed as mean  $\pm$  SEM. Statistical analyses were performed using GraphPad Prism Software 7.0.

Fig. 6. Effects of MLNC-AnxA1 treatment on epithelial regeneration and renovation in the colon damaged by DSS-induced colitis. Ki67 and PCNA are represented in 20x and 40x high-power objective. (A and G) Naive group; (B and H) DSS group; (C and I) AnxA1 group; (D and J) MLNC group; (E and K) MLNC-AnxA1 group. The quantification of proliferative nuclei stained with Ki67 (F) and PCNA (L) are presented in the graphs.  $n = 6$  mice/group. Sections:  $4 \mu\text{m}$ . Bars:  $50 \mu\text{m}$  and  $20 \mu\text{m}$ . \*  $p < 0.05$  vs DSS. &  $p < 0.05$  vs MLNC. Abbreviations: PCNA, Proliferating Cell Nuclear Antigen.

### 3. Results

#### 3.1. Development of nanocapsules

All formulations showed white-opalescent homogeneous macroscopic aspect, with no visible aggregation in storage vials. Three individual batches of LNC, MLNC or MLNC-AnxA1 were prepared. After the addition of chitosan, the z-average diameters of MLNC and MLNC-AnxA1 presented values greater than the mean diameter of LNC ( $p < 0.05$  and  $p < 0.01$  respectively) (Table 1; Fig. 1). PDI was significantly higher for the MLNC and MLNC-AnxA1 formulations (moderate polydispersity) when compared to the LNC (narrow polydispersity) ( $p < 0.001$ ). Comparing MLNC and MLNC-AnxA1 formulations, the latter presented a lower polydispersity index ( $p < 0.05$ ) (Table 1; Figure S2). PDI of the 3 formulations was lower than 0.3. The zeta potential was inverted after the addition of chitosan ( $p < 0.001$ ), and no difference was observed between the chitosan-containing nanocapsules (MLNC and MLNC-AnxA1) (Table 1, Fig. 1). The addition of chitosan to the LNC structure caused a significant pH reduction when compared to the other groups ( $p < 0.01$ ), an expected result since acetic acid is used to disperse the chitosan solution (Table 1).

Furthermore, using 2D plots (intensity of light scattering versus diameter), nanoparticle tracking analysis showed that MLNC-AnxA1 overlap MLNC (Figure S3), demonstrating that conjugation with the protein occurred efficiently, and no aggregation occurred after forming the organometallic complex. Coordination efficiency of AnxA1 ( $92.22 \pm 1.47\%$ ) was calculated after ultrafiltration-centrifugation and quantification of unconjugated protein. TEM photomicrographs (Fig. 1) demonstrated MLNC-AnxA1 spherically shaped. The aspect of those nanocapsules were similar to other chitosan-coated nanocapsule formulations previously published [30,37].

#### 3.2. Intraperitoneal injection of MLNC-AnxA1 attenuates ulcerative colitis

DSS ingestion induced colitis as observed by clinical parameters weight loss, diarrhea score and occult blood in stool, bowel length and DAI. Treatments with AnxA1 or MLNC-AnxA1 by oral route did not attenuate the damage caused by DSS ingestion (Figure S4). Only i.p. treatment with MLNC-AnxA1 was effective in reducing the symptoms of ulcerative colitis. It was observed reduced weight loss, diarrhea and disease activity index (Fig. 2A–D), as well as restoration of the colonic structure integrity, as demonstrated by the intestine length recovery at day 10 after DSS ingestion (Fig. 2E–F).

#### 3.3. MLNC-AnxA1 treatment modulates macrophage phenotype in intestinal lamina propria

The characterization of cells isolated from the lamina propria demonstrated that DSS ingestion markedly increased the number of neutrophils (Ly6G<sup>+</sup>; Fig. 3A) and macrophages (F4/80<sup>+</sup>; Fig. 3B), which reflected increased amount of M1 macrophages (F4/80/CD80<sup>+</sup>; Fig. 3C). None of the treatments reduced the amounts of neutrophils and macrophages (Fig. 3A and 3B); nevertheless, MLNC-AnxA1 treatment reduced the amount of M1 macrophages (F4/80/CD80<sup>+</sup>; Fig. 3C) and both AnxA1 and MLNC-AnxA1 treatments elevated the amount of M2 macrophages (F4/80/CD206<sup>+</sup>; Fig. 3D).

Based on these results, we further investigated if MLNC or MLNC-AnxA1 were up-taken by macrophages. Data presented in Figure S5, obtained in CytoViva experiments, showed cultured Raw 264.7 cells taken up both nanocapsule preparations 24 hs after incubation. Moreover, to test the efficacy of taken up, we investigated the mice bone marrow macrophages polarization into M2 phenotype, as AnxA1 switches macrophage into M2 cells. As visualized in the Figure S6, dexamethasone (positive control of the experiment) and MNLC induced M2 polarization; nevertheless MLNC-AnxA1 effect was higher in

comparison to those groups of cells. In addition, only MLNC-AnxA1 treated cells secreted higher amounts of TGF- $\beta$ , a pro-resolution mediator secreted by M2 cells (Figure S6). It is noteworthy to mention, AnxA1-treated cells did not switch cells into M2 profile, reinforcing the importance AnxA1 encapsulation in the MLNC.

#### 3.4. MLNC-AnxA1 treatment improves histological recovery, expression of proteins related to epithelial proliferation and structure

DSS ingestion caused severe damage to the colonic tissue of mice; untreated mice reached the highest histological score (Fig. 4A, C and D) in all parameters: tissue edema (dotted line), dysplasia/altered histoarchitecture (black arrow head), crypt edema (yellow arrow head), inflammatory infiltrates (white arrow head) and ulcerations (black arrow). MLNC-treated mice showed high histological scores, similar to seen for the DSS group (Fig. 4G and H), while AnxA1 treatment elicited improvements on histological scores, reducing some parameters as edema and dysplasia/altered histoarchitecture (Fig. 4E and F). However, only MLNC-AnxA1 treatment led to recovery of the colonic histoarchitecture during colitis, decreasing crypt edema, inflammatory infiltrates and ulcerations, and restoring tissue histoarchitecture in comparison with the DSS group (Fig. 4I and J). Also, the naïve group showed a normal histoarchitecture as expected (Fig. 4B).

Moreover, the area stained for tight adhesion molecules claudin-1 and ZO-1 was reduced in DSS mice (Fig. 5B and G) when compared with naïve group (Fig. 5A and F) and treatments with AnxA1 and MLNC-AnxA1 restored the expression of Claudin-1 (Fig. 5H and J) and MLNC-AnxA1 treatment restored the expression of ZO-1 (Fig. 5E) in inflamed tissues. In addition, AnxA1 and MLNC did not restore the ZO-1 expression (Fig. 5C and D) and MLNC showed the same result as DSS to the expression of claudin-1 (Fig. 5D).

Additionally, the number of proliferative nuclei in the mucosal layer was assessed by counting PCNA and Ki67 positive cells (Fig. 6F and L). PCNA and Ki67 are nuclear proteins; PCNA participates in DNA synthesis and repair pathways, while Ki67 is involved in cell proliferation and ribosomal RNA transcription. For both targets, only treatment with MLNC-AnxA1 increased the number of positive nuclei, mostly in the basal region, indicating regenerative epithelium (Fig. 6E and K). In other treatment groups, there was a low number and structural disorganization of PCNA (Fig. 6G, H, I and J) and Ki67 (Fig. 6A, B, C and D) positive cells, which became irregularly distributed throughout the extension of epithelial cells. Moreover, increased staining in the apical zone of tissue was found in DSS, AnxA1 or MLNC treated groups, indicating areas of dysplasia.

### 4. Discussion

Development of novel approaches for treatment of IBDs is a collective effort of a massive number of researchers worldwide, considering chronicity and relapsing features of such diseases. Moreover, patients are not always responsive to current pharmacotherapy, and the physical and psychosocial symptoms associated with high costs of medication burdens health care systems [38]. Based on our previous data showing multi-wall LNC (MLNC) as effective tools to functionalize proteins [32,39], we here employed MLNC to functionalize recombinant Annexin A1 (AnxA1), a known anti-inflammatory and tissue repair protein secreted by inflammatory and epithelial cells during IBDs [19,14–16,40–42]. AnxA1 was efficiently functionalized onto MLNC, and MLNC-AnxA1 administered into the peritoneum of mice reduced disease symptoms and improved gut tissue recovery in mice-induced colitis. These effects were not evoked by non-functionalized AnxA1, highlighting the functionalization of AnxA1 into MNLC as a tool to improve local anti-inflammatory and repairing tissues properties of the protein.

The MLNC-AnxA1 supramolecular structure here employed comprises LNC containing polyester as the first wall, coated with a negative

layer of lecithin containing phosphatidic acid that is covered by a chitosan wall generating electrostatic interactions. The incorporation of chitosan was confirmed by the inversion of the zeta potential, by slightly enhancing values of z-average diameters comparing MLNC and MLNC-AnxA1 to LNC. Chitosan is pivotal for coordination of metals within specific protein chemisorption sites. Indeed, the unimodal nanometric profile after protein addition showed high affinity between AnxA1 and  $Zn^{2+}$ , and the efficiency of coordination of 92 % confirmed the protein chemisorption at the nanocapsule surface. Mean diameters lower than 200 nm, PDI lower than 0.3 and satisfactory TEM images ensure investigation of biological activity of MLNC-AnxA1 is feasible.

A pivotal challenge was to test the effectiveness of oral administration of MLNC-AnxA1 on colitis, as we hypothesized the supra molecular structure achieved by the multi wall and the covalent binding of the protein to the metal would be robust enough to protect AnxA1 from degradation inside the gastrointestinal compartments. Previous study using the same nanotechnology here employed showed high bioavailability of MLNC-captopril-furosemide by oral route, which was highly efficient in reducing hypertension in comparison to treatments with non-functionalized drugs [33]. Oral administration of MLNC-AnxA1 did not affect the symptoms of colitis. Therefore, it may be inferred *in vivo* actions of physiological components within the gastrointestinal compartments could have displaced the protein from the supra molecular structure and further inactivate it.

Conversely, i.p. administration of MLNC-AnxA1 inhibited the development of main colitis symptoms, the DAI being lower after four treatment doses. Histological analyses corroborated the higher effectiveness of MLNC-AnxA1 in causing tissue recovery. Non-functionalized AnxA1 was not so efficient in restituting epithelial membrane and crypt reorganization as MLNC-AnxA1. These data, alongside the recovery of gut length in MLNC-AnxA1 treated mice, suggest functionalized AnxA1 exerted mechanisms of wound healing.

The onset of epithelial healing in IBD is characterized by rapid migration of epithelial cells in order to reorganize rudimentary barriers, which is followed by influx of inflammatory cells into the lamina propria. Morphological changes of crypts, showing bifurcating/branching structures, and stem cell proliferation supports wound closure, characterized by restitution of the normal pattern of epithelial structure, cellular differentiation, and barrier function [43]. The complexity of cell and molecular mechanisms in wound healing in IBDs involves a broad diversity of targets as markers of the process. We here chose to quantify the profile of immune cells in the lamina propria, expression of tight junction (TJ) molecules involved with epithelial permeability, and markers of cell proliferation.

TJ are expressed at the top of the lateral membrane of intestinal epithelial cells keeping them together as a barrier, forming channels that allow passage between cells and also activate intracellular signaling [44]. Zonula Occludens-1 (ZO-1) is a pivotal regulatory TJ protein for gastrointestinal hemostasis, and alterations on ZO-1 affect expression and functions of other TJ [45]. Therefore, stable dynamic levels of ZO-1 protein are fundamental for normal function of the epithelial barrier. ZO-1 expression was reduced in epithelium of DSS-induced colitic mice, which was rescued to normal levels by MLNC-AnxA1 treatment. Although values were not significantly different, MLNC and Annexin A1 treatments also enhanced ZO-1 expression [46]. Indeed, it has been shown that oral administration of higher doses of chitosan during the resolutive phase of inflammation improved recovery of clinical and histological parameters, including expression of ZO-1 [42]. Claudin-1, also a TJ protein, plays a relevant role in intestinal homeostasis but regulation of its expression depends on type of IBD disease and in which stage it finds itself in regarding symptoms [44,47]. In our model of colitis under our schedule of treatments, claudin-1 expression was reduced and localized in the damaged epithelium of DSS mice group. MLNC-AnxA1 treatment increased the expression of claudin-1, especially in reorganized crypts. Therefore, data herein demonstrated evidence AnxA1, mainly the one released by MLNC, promotes expression of TJ

proteins in order to reestablish crypt structure. In fact, the physiological actions of AnxA1 on TJ have been demonstrated in endothelial cells of the blood brain barrier [48], in which deficient expression of the protein is related to the genesis of neurodegenerative diseases. In these cases, acute treatment with AnxA1 rescues TJ expression and ameliorates the development of brain diseases [48–51]. Furthermore, *in vitro* AnxA1 treatment enhanced the expression of both claudin-1 and ZO-1 in uterine epithelium during blastocyte attachment [52]. Associated, these data support AnxA1 as a pivotal protein for stabilizing TJ, and here we show, for the first time, the effect of functionalized AnxA1 on rearrangement of gut epithelial TJ during colitis.

Corroborating the reorganization of crypts visualized in animals treated with MLNC-AnxA1, treatment with the functionalized AnxA1 enhanced the proliferation in the region where transit-amplifying cells and stem cells are localized, at the bottom of crypts and constitute a signaling center that is a pivotal factor for tissue growth [53]. In addition, the treatment with MLNC-functionalized AnxA1 reduced the proliferation of cells extends to the apical tissue. This effect is observed in disorganized growth and proliferated cells approximately two-thirds of the crypt length can indicate dysplasia. It is also a favorable effect as proliferating cells in PCNA and Ki67 labeling in the damaged tissue indicate dysplasia [54–58].

Taken together, data here depicted highlight the functionalization of AnxA1 as a possible adjuvant to therapeutic approaches employed on IBDs treatment. Previous data had already shown the high effectiveness of nanoparticles loading AnxA1 mimetic peptide Ac2-26 on experimental colitis [16,59] validating further studies.

## 5. Conclusion

Experimental data provided in this study corroborated the ability of multi-wall LNC functionalization as a tool for delivery of hydrophilic molecules into target tissues. Moreover, the findings support the development of nanoparticles containing AnxA1 to drive it into damaged intestine areas, as it provides effective anti-inflammatory and pro-resolving actions in tissue repair. Short treatment period with area-focused low concentrations of AnxA1 may be an efficient strategy to improve tissue recovery during the relapsing acute inflammatory crisis in IBDs. Nevertheless, further studies must still be carried out to evaluate the risks and benefits of this approach.

### ABSTRACT

**Background:** Omega 3 fatty acids, such as docosahexaenoic acid (DHA) have been widely consumed as supplements to control chronic inflammation. Nanocapsules containing DHA (MLNC-DHA- $\alpha$ 1) were developed and showed excellent stability. Thus, our objective was to evaluate the effect of MLNC-DHA- $\alpha$ 1 nanocapsules on biomarkers of chronic inflammation.

**Method:** Cells viability was determined by flow cytometry. The uptake of MLNC-DHA- $\alpha$ 1 nanocapsules by macrophages and their polarisation were determined. *In vivo*, *LDLr*<sup>-/-</sup> mice were fed a Western diet to promote chronic inflammation and were treated with MLNC-DHA- $\alpha$ 1 nanocapsules, intravenously injected via the caudal vein once a week for 8 weeks.

**Results:** MLNC-DHA- $\alpha$ 1 nanocapsules decreased the concentration of TNF $\alpha$  ( $p = 0.02$ ) in RAW 264.7 cells compared to the non-treated group (NT), with no changes in IL-10 ( $p = 0.29$ ). The nanocapsules also exhibited an increase in the M2 (F4/80<sup>+</sup> CD206) phenotype ( $p < 0.01$ ) in BMDM cells. *In vivo*, no difference in body weight was observed among the groups, suggesting that the intervention was well tolerated. However, compared to the CONT group, MLNC-DHA- $\alpha$ 1 nanocapsules led to an increase in IL-6 ( $90.45 \times 13.31$  pg/mL), IL-1 $\beta$  ( $2.76 \times 1.34$  pg/mL) and IL-10 ( $149.88 \times 2.51$  pg/mL) levels in plasma.

**Conclusion:** MLNC-DHA- $\alpha$ 1 nanocapsules showed the potential to promote *in vitro* macrophage polarisation and were well-tolerated *in vivo*. However, they also increased systemic pro-inflammatory cytokines. Therefore, considering that this immune response presents a limitation for clinical trials, further studies are needed to identify the specific compound in MLNC-DHA- $\alpha$ 1 that triggered the immune response. Addressing this issue is essential, as MLNC-DHA- $\alpha$ 1 tissue target nanocapsules could contribute to reducing chronic inflammation.

### 1. Introduction

Chronic inflammatory conditions lead to several diseases that collectively represent the leading causes of disability and mortality worldwide, such as cardiovascular disease, cancer, diabetes mellitus, chronic kidney disease, non-alcoholic fatty liver disease, autoimmune and neurodegenerative disorders [1–4]. In these examples, the

long-lasting chronic inflammation is a result of the signaling promoted by cells of the innate and adaptive immune system, as response to the presence of damage-associated molecular patterns (DAMPs) in the blood stream or inside the host cells and tissues [1,5].

The reaction of the immune system cells to various types of DAMPs is complex and difficult of controlling. For this reason, in many cases, due to discomfort, pain or even risk of more severe complications, the

systemic inflammation is suppressed by drugs. However, non-steroidal anti-inflammatory drugs (NSAIDs) or glucocorticoids, have many adverse effects [6–10], and their continuous intake can increase the individual susceptibility to infections [11,12].

In this context, pharmacological strategies based on bioactive compounds could provide an interesting alternative to complement drug prescriptions, thereby improving the quality of life for patients. Among the bioactive lipids, it has been reported the anti-inflammatory effects attributed to omega-3 fatty acids, particularly eicosapentaenoic acid (C20:5 n3; EPA) and docosahexaenoic acid (C22:6 n3; DHA) [13]. EPA and DHA exert anti-inflammatory activity by replacing arachidonic acid (AA) in the phospholipids, leading to produce less potent prostaglandins, prostacyclins, leukotrienes and thromboxanes after the activation of cyclooxygenases (COX) and lipoxygenases (LOX) [13,14]. In addition, EPA and DHA can inhibit the translocation of the nuclear factor NF-kappaB (NFkB) to the nucleus through Peroxisome proliferator-activated receptor gamma (PPARγ) depending mechanisms, reducing the expression of genes encoding pro-inflammatory molecules [14–16]. It has also been reported that EPA and DHA suppress the inflammasome pathway, decreasing the Interleukin 1β (IL1β) maturation and release, and they can also serve as substrates for the synthesis of specialized pro-resolving mediators (SPMs), such as resolvins, protectins and maresins, capable of resolving the inflammatory process [2,3,17–19]. In fact, EPA and DHA may possess preventive and therapeutic potential in managing chronic inflammatory diseases [16], and new nanotechnology-based strategies have been developed to deliver omega-3 fatty acids to target tissues [20].

On the other side, strategies involving general immunosuppression have shown some important limitations, because inflammation is essential to protect individuals also against pathogens-associated molecular patterns (PAMPs) and damage-associated molecular patterns (DAMPs) [1,2]. One example is a study published by Ridcker et al., in which patients with cardiovascular disease treated with Interleukin-1β

monoclonal antibody showed a reduction of cardiovascular events, but had more infections caused by the systemic suppression of the immune system [21]. Thus, it is necessary to develop alternatives for reducing chronic inflammation without inhibiting the immune system's ability to protect the body against new infections. One alternative is the application of nanotechnology-based drug delivery systems to deliver anti-inflammatory compound straightly to the target tissue. Nanoparticle-mediated drug delivery systems have been used in anti-inflammatory therapies, reducing medical dosage and improving therapeutic effectiveness [22].

In a previous study carried out by our group [23], anti-PEGAM-1-surface-functionalized metal-complex multi-wall nanocapsules containing DHA richer algae oil in their core (MLNC-DHA-a1) were developed, showed a 94.80% conjugation efficiency and did not show significant toxicity towards HUVEC cells. Thus, our hypothesis, as summarized in Fig. 1, is that MLNC-DHA-a1 nanocapsules could be engulfed by the macrophage as a DAMP, their lipid content hydrolyzed by lysosomal lipases, releasing non-esterified fatty acids (NEFA) such as DHA for generation of lipid mediators [24]. Upon Toll-like receptor 4 (TLR4) activation, there is a rapid decrease in the cellular content of polyunsaturated fatty acids due to increased phagocytic activity, endoplasmic reticulum enlargement and synthesis of oxylipins [25]. Thus, it is supposed that the DHA supplied by our nanocapsules can be rapidly oxidized by cyclooxygenase, 5-lipoxygenase and cytochrome P450 (CYP), leading to the synthesis of anti-inflammatory oxylipins, including Specialized Pro-Resolving Mediators (SPMs) [25,26]. SPMs modulate the phenotype conversion of M1 into M2 macrophages, contributing to the resolution of inflammation [27]. In addition, the increase of DHA/AA ratio can reduce the inflammation by other mechanisms [13].

Given the hypothesis outlined in Fig. 1, it is important to evaluate the cytotoxicity, determine the *in vitro* effect of these nanocapsules on macrophage uptake and polarization, and to evaluate the tolerance of the animals to the nanocapsules injections and their inflammatory

**Fig. 1.** Summary of the strategy proposed in this study. The surface-functionalized (anti-PEGAM-1) metal-complex multi-wall nanocapsules containing algae oil as DHA source (MLNC-DHA-a1) could be internalized by the macrophages, promoting a higher DHA/AA ratio inside the cell compared with non-treated samples. As consequence, MLNC-DHA-a1 supplemented cells could show an anti-inflammatory condition associated to M2 polarization, leading to a higher plaque stability. response in plasma and liver after the treatment.

## 2. Material and methods

### 2.1. Materials

Lipid-core nanocapsules containing DHA (LNC-DHA), multi-wall nanocapsules containing DHA (MLNC-DHA) and the surface-functionalized (anti-PECAM-1) metal-complex multi-wall nanocapsules containing DHA (MLNC-DHA-a1) were prepared and characterized in our previous study [23] (Fig. S1). Algae oil applied in the oral supplementation (DHASCO™) was purchased from DSM (Heerlen, Netherlands). Medium-chain triacylglycerol (MCT) was purchased from Nutrimea Ind. Ltda (São Paulo, Brazil). Honey was supplied by Apis-Nutri Ltd. (Mandaguari, Brazil). The fatty acid composition of the algae oil and MCT were previously described in another study published by our group [23].

### 2.2. Methods

#### 2.2.1. Cell culture

RAW 264.7 (immortalized murine macrophages) cells were obtained from the Rio de Janeiro Cell Bank (BCRJ, Rio de Janeiro, RJ, Brazil) and cultured in DMEM (Gibco, Grand Island, NY, USA) high glucose (4500 µg/mL) containing 10% FBS. Cells were kept at 37 °C under a controlled CO<sub>2</sub> atmosphere of 5%. Cell's culture medium was replaced every 2–3 days and the cells were trypsinized with 0.01% trypsin in EDTA buffer (Vitrocell Embriolife, Campinas, SP, Brazil).

#### 2.2.2. Cell viability

The cytotoxicity of the nanocapsules was evaluated using a flow cytometer after culturing. Briefly, cells were seeded at  $2.5 \times 10^4$  cells/well in 24-well microplates (Costar® Multiple Well Cell Culture Plates, Corning, Glendale, Arizona, USA) and kept at 37 °C for 24 h. Afterward, cells were treated with LNC-DHA; MLNC-DHA and MLNC-DHA-a1 (Fig. S1) at three concentrations: 0.14, 0.75 and  $1.40 \times 10^{11}$  nanoparticles/mL, and cultured for 24, 48 and 72 h. Isolated anti-PECAM-1 was also evaluated at a 200 µg/mL concentration. After that, cells were detached and washed twice in phosphate-buffered saline containing 1% bovine serum albumin. Next, cells were incubated with Annexin V (previously diluted (1:20) in Annexin V (Life Technologies, Carlsbad, USA) binding buffer (10 mM N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid, 140 mM NaCl, 25 mM CaCl<sub>2</sub>, pH 7.4; BD Pharmingen, Franklin Lakes, NJ) during 20 min in the dark, at room temperature. After this, 200 µL Annexin V binding buffer and 7-AAD (1:200) were added. Data from 10,000 events were acquired in an Accuri C6 flow cytometer (BD Pharmingen), and the stained cells were analyzed. The negative double group for AnxV and 7-AAD (non-apoptotic and non-necrotic) marking was plotted to quantify the cell viability (AnxV-, 7-AAD -), single marking with AnxV represented cells in apoptosis (AnxV+, 7-AAD -), single marking with 7-AAD indicated cells in necrosis (AnxV-, 7-AAD+), while the double group positive for AnxV-7-AAD denoted the group of cells in late apoptosis (AnxV+, 7-AAD+). The results of triplicates were expressed as a percentage (%).

#### 2.2.3. Real-time uptake of the nanocapsules by RAW 264.7 macrophages

The uptake of nanocapsules by macrophages was determined by enhanced dark-field hyperspectral microscopy (CytoViva®) as described by Sandri et al. [28]. First, RAW 264.7 murine macrophages ( $8 \times 10^4$  cells) were seeded in extra clean dust-free Nexterion® Glass D coverslips (#D263T; Schott, New York, NY, USA) present in 96-well plates (Corning, NY, USA). After adherence, cells were incubated with a medium containing MLNC-DHA and MLNC-DHA-a1 at  $0.75 \times 10^{11}$  nanoparticles/mL for 4 h at 37 °C under a 5% CO<sub>2</sub> atmosphere. A non-treated group (NT) was kept in DMEM 10% FBS. Immediately after incubation, cells were washed three times with 5% FBS-PBS, and the coverslip was

placed on extra clean dust-free Nexterion® Glass B slides (NexterionR Glass B; Schott, NY, EUA) containing 10 µL of 5% FBS-PBS. Then, 10 µL of cell solution were set up using extra clean dust-free slides (NexterionR Glass B; Schott, NY, USA) and coverslips (Nexterion Glass D #D263T; Schott). RAW 264.7 murine macrophages were imaged using a CytoViva Ultra Resolution Imaging System (CytoViva, Inc., AL, USA) mounted on an Olympus BX51 microscope (x1500 magnification; Olympus Corporation, Tokyo, Japan) equipped with fluorite 100 × oil iris 0.6–1.30 numerical aperture (NA) objective and a 75 W Xe light source. Optical images were taken using a Dage XL CCD digital camera with Image Processing Software (Dage ®; DAGE-MTI of MC, Inc., MI, USA). ImageJ software, version 2.1.0/ 1.53c (2010–2022), was used to place the scale bars. One hundred cells from representative photomicrographs were randomly chosen for this measurement and each treatment.

#### 2.2.4. Macrophage polarization

The experiment was performed according to the method previously established by Ying et al. [29]. Initially, C57BL/6 mice were anesthetized and euthanized to collect the left and right femurs for medullary washes collection, using an icy PBS solution containing 2% Fetal Bovine Serum (FBS). All animal experiments were conducted under the National Institutes of Health guidelines and were approved by the Institutional Animal Care and Use Committee of FCF/USP. Then the bone marrow pool was resuspended using 21 G needles to dissociate the cells and pass them through a 70 µm cell strainer to remove other tissues. The cells were washed with NH<sub>4</sub>Cl 0.8% solution and incubated in ice for red cell removal. After centrifugation for 5 min, 500 × g at 4 °C, the cells were resuspended with bone marrow-derived macrophages (BMDM) medium, composed of IMDM (Isocove Modified Dulbecco Media), 20% L929 cell culture rich in monocyte growth factor (M-CSF) and 10% of FBS. The cells were counted and plated at the concentration of  $5 \times 10^5$  cells/well in a 24-well plate and maintained in BMDM medium for 7 days for cell differentiation. After this period, and considering that this time provides 90% of macrophage differentiation, naive cells were exposed to *Escherichia coli* (LPS) 100 ng/mL and maintained for 24 h to generate the M1-inflammatory phenotype macrophage. Treatments were performed with dexamethasone (500 ng/mL), MLNC-DHA ( $0.75 \times 10^{11}$  particles/mL) or MLNC-DHA-a1 ( $0.75 \times 10^{11}$  particles/mL containing 200 µg/mL of Anti-PECAM-1). After 48 h, the supernatant was removed and cytokines were analyzed by ELISA assay according to the manufacturer's instructions. Single-cell suspensions were prepared at  $2 \times 10^7$  cells/mL in staining buffer (10% FCS in PBS) and pre-incubated with 1 µg of the 2.4G2 antibodies for 5–10 min on ice prior to staining. About 50 µL of cell suspension (equal to  $10^6$  cells) were dispensed into each tube or well along with a previously determined optimal concentration of cell surface specific antibody against F4/80<sup>+</sup> CD80 and F4/80<sup>+</sup> CD206 for differentiation of M1 and M2 macrophages respectively, in 50 µL of staining buffer. Cell surface expression of these maturation markers was measured on BD opteia™ kits (BD Biosciences). The collected events were analyzed with FlowJo v7.6 (Treestar).

#### 2.2.5. Animal protocol

Three-month-old male homozygous LDLr<sup>-/-</sup> mice in the C57BL/6 background were purchased from the Faculty of Pharmaceutical Sciences, University of São Paulo. The animals were divided into 5 groups and kept for 24 weeks under a Western diet *ad libitum*. After this period, one group (BASELINE) was euthanized (n = 10), and the diet of the other groups was replaced by AIN93M regular diet [30] for 8 weeks (Fig. S2). The animals were kept at 25 ± 2 °C and relative humidity of 55 ± 15% in an inverted cycle of 12 h light/12 h dark. Diet formulation and chemical composition is shown in Supplementary material (Table S1 and Table S2), respectively. Food intake and animal weight were weekly measured. During the last 8 weeks, DHA-D group (n = 9) was supplemented with algae oil by gavage. Algae oil (0.011 mL) was mixed with 0.094 mL of honey and 0.094 mL of soybean oil to reduce the gavage stress [31]. This mixture (0.20 mL) was given to each animal

once a week, and the dose was based on 1.8 g/day for humans [32]. CONT group (n = 11) had no supplementation. The MLNC-DHA-a1 group (n = 15) received  $5.36 \times 10^8$  surface-functionalized (anti-PECAM-1) metal-complex multi-wall nanocapsules containing 12  $\mu\text{L}$  algae oil/mL and LNC-MCT group (n = 15) received  $1.09 \times 10^8$  lipid-core nanocapsules containing 12  $\mu\text{L}$  MCT/mL, intravenously injected via caudal vein once a week. The body weight of the animals at the beginning of the intervention was  $47.03 \pm 0.62$  g. Thus, the dose of DHA provided by diet or nanocapsules were  $28.57 \text{ mg} \approx 10 \text{ mg DHA Kg bw/day}$  and  $0.0011 \text{ mg} \approx 0.0004 \text{ mg DHA Kg bw/day}$ , respectively. After this second period, mice were anesthetized with isoflurane and euthanized. Blood samples were collected after the euthanasia, transferred to EDTA (1%) vacutainer tubes, and centrifuged at  $3000 \times g$  for 10 min at  $4^\circ\text{C}$ . Tissues and plasma were frozen in liquid nitrogen and stored at  $-80^\circ\text{C}$  for analysis.

### 2.2.6. Plasma metabolites

The concentration of plasma lipids, including total cholesterol (TC), triglycerides (TG), high-density lipoprotein (HDL), low-density lipoprotein (LDL), besides glucose, aspartate transaminase (AST) and alanine transaminase (ALT) was quantified using commercial kits from Labtest Diagnóstica SA (Lagoa Santa, Brazil).

### 2.2.7. Inflammatory and oxidative stress biomarkers

The cytokines concentration, including interleukin-6 (IL-6), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-10 (IL-10) and interleukin 1 $\beta$  (IL-1 $\beta$ ), was quantified in plasma and liver homogenate, using MILLI-PLEX MAP Mouse Cytokine/Chemokine Magnetic Bead Panel (MCTOMAG-70 K) (Millipore, St. Charles, MO, USA). The protein content of the homogenates was quantified by Bradford methodology. Malondialdehyde (MDA) concentration was determined by reverse phase HPLC according to Hong et al. [33] and analyzed using a Phenomenex reverse-phase C18 analytical column (250 mm  $\times$  4.6 mm; 5 mm; Phenomenex) with an LC8-D8 pre-column (Phenomenex AJ0-1287) coupled to an HPLC (Agilent Technologies 1200 Series). A standard curve was prepared using 1,1,3,3-Tetraethoxypropane (TEP, T9889 Sigma-Aldrich), and data were expressed as nmol/mg protein.

### 2.2.8. Fatty acids proportion

Fatty acids were determined in the liver homogenates and plasma according to Shirai et al. [34] using a gas chromatography coupled with a triple quadrupole mass spectrometer (GC-MS Agilent 7890 A GC System, Agilent Technologies Inc., Santa Clara, USA). Fatty acids were separated on a fused silica capillary column (J&W DB-23 Agilent Inc. Santa Clara, USA). Compounds were identified by comparing the retention time of fatty acids in the samples with the retention time of standards (FAME 37 Component Mix Supelco 47885) and also based on a comparison of their mass spectra with those given in the spectral database of the National Institute of Standards and Technology (NIST, Gaithersburg, MD, USA). One analysis was carried out/animal, and the fatty acid/IS (C23:0, Fluka 91478) area ratio was applied to calculate the percentage of each fatty acid.

### 2.2.9. Statistical analysis

Data were presented as mean  $\pm$  SEM. Treatments were compared using one-way ANOVA and Tukey HSD post-test or non-parametric Kruskal-Wallis ANOVA by Ranks, followed by Multiple Comparisons (2-tailed). T-test or Mann-Whitney test were applied to compare BASELINE and CONT groups. A *p*-value of 0.05 was adopted to reject the null hypothesis. Calculations will be performed using Statistica v.13 (TIBCO Software Round Road, TX, USA). Graphs were elaborated using R Studio and GraphPad Prism v9 (GraphPad Software, CA, USA).

## 3. Results

### 3.1. In vitro assays

The toxicity of the nanocapsules was determined using RAW 264.7 murine macrophages (Fig. 2). The results showed that the viability of the cells incubated with three concentrations of nanocapsules for 24 h (Fig. 2A), ranged from  $52.36 \pm 17.62\%$  to  $83.33 \pm 1.59\%$ , but did not differ among themselves (*p* = 0.39) (Fig. 2B). A similar trend was observed after 48 h (Fig. 3) and 72 h (Fig. 3A). Although no statistically differences were observed, we opted to proceed with the concentration of  $0.75 \times 10^{11}$  nanocapsules/mL was for the subsequent assays to minimize any potential toxicological risk. Fig. 3 shows that all nanocapsules were internalized as a damage-associated molecular pattern (DAMP) by RAW 264.7 macrophages, according to the strategy proposed in our hypothesis (Fig. 1). In the next step, BMDM cells were applied to evaluate macrophage polarization. As shown in Fig. 4, internalization of MLNC-DHA and MLNC-DHA-a1, led to a reduction in TNF- $\alpha$  compared with NT cells (*p* = 0.01) (Fig. 4A), while no difference was observed to IL-10 (*p* = 0.29) (Fig. 4B). Regarding to macrophage polarization, treatments with dexamethasone or nanocapsules did not change the M1 phenotype (*p* = 0.25) (Fig. 4C). However, MLNC-DHA-a1 enhanced (*p* < 0.01) M2 phenotype compared with NT cells, while MLNC-DHA showed a trend to increase it (*p* = 0.06) (Fig. 4D), suggesting the beneficial effect of the nanocapsule in promoting macrophage switch phenotype.

### 3.2. In vivo assays

This is the first *in vivo* study that applies a surface-functionalized nanocapsule containing algae oil in the core. For this reason, our first challenge was to evaluate if weekly caudal injections could influence diet intake and, consequently, body weight gain of the animals. In our experimental protocol, all groups received a Western diet for 24 weeks. After, about two to three animals were selected from each group to compose the BASELINE (n = 10) group, while the remaining animals were divided into four groups (n = 9–15) and received a regular diet for 8 weeks. There was no difference among the groups at the beginning ( $25.74 \pm 0.31$  g, *p* = 0.32, *n* = 57), nor after 24 weeks under a Western diet containing about 36% lipids ( $47.03 \pm 0.62$  g, *p* = 0.57, *n* = 56). The same was observed among the 4 groups receiving a regular diet after 32 weeks ( $35.39 \pm 0.65$  g, *p* = 0.49, *n* = 47) (Fig. 5SA). Neither Western diet ( $2.40 \pm 0.04$  g pc, *p* = 0.96) nor regular diet intake ( $3.02 \pm 0.22$  g pc, *p* = 0.26) changed according to the groups (Fig. 5SB). The use of a Western diet in LDL<sup>-/-</sup> mice is a classical model for inducing inflammation and promoting lipid profile alteration. In our model, the Western diet caused the increase of TC, LDL, HDL, TG, ALT, IL-1 $\beta$  concentration in plasma, and TNF $\alpha$  (*p* = 0.05) in liver homogenate (Table 5B). However, 8 weeks after discontinuing the stimulus, except for IL-1 $\beta$ , the other measured cytokines in plasma and liver did not change, suggesting a maladapted post-resolution condition.

After 24 weeks, the inflammatory stimulus was removed by replacing the Western diet with a regular diet, and the effect of the oral interventions with algae oil (DHA-D) and the functionalized nanocapsules (MLNC-DHA-a1) was compared in terms of lipid profile and oxidative stress. Table 1 describes the major fatty acids profiles determined in the animals after 32 weeks, both in liver homogenate and plasma. No important changes were observed in the proportion of fatty acids analyzed in plasma among the groups. In the liver, DHA-D group that received algae oil supplementation by gavage showed a higher proportion of DHA compared with CONT (*p* = 0.02), but not compared with MLNC-DHA-a1 (*p* = 0.18) (Table 1). This result suggests that some of the DHA from the surface-functionalized nanocapsules reached the liver, but it was not enough to increase DHA proportion compared to CONT (*p* = 0.35). Furthermore, no alteration was observed in the relative liver weight ( $0.04 \pm 0.00\%$ , *p* = 0.45).

**Fig. 2.** RAW 264.7 murine macrophages viability, necrosis, apoptosis and late apoptosis as estimated by flow cytometry after culturing incubated with LNC-DHA, MLNC-DHA and MLNC-DHA-a1 at three concentrations ( $0.14 \times 10^{11}$ ,  $0.75 \times 10^{11}$  and  $1.40 \times 10^{11}$  /mL), also incubated without any nanocapsules (NT) and isolated anti-PECAM-1 at 200 µg/mL for 24 h. **Fig. 2A:** Flow cytometry colocalization of annexin-V binding and propidium iodide uptake for quantitation of RAW 264.7 murine macrophages incubated with MLNC-DHA-a1, as example. The horizontal axis depicts fluorescein-labeled annexin V; the vertical axis shows binding of propidium iodide fluorescence. **Fig. 2B:** Proportion of RAW 264.7 murine macrophages viability, necrosis, apoptosis and late apoptosis. Vertical bars are mean  $\pm$  SEM ( $n = 3$ ). No difference was observed among the samples according to cell viability ( $p = 0.94$ ), necrosis ( $p = 0.66$ ), apoptosis ( $p = 0.75$ ) and late apoptosis ( $p = 0.48$ ) by Kruskal Wallis analysis.

**Fig. 3.** Three-dimensional Cytoviva microscopy images of uptake performed in RAW 264.7 murine macrophages after 2 h of incubation with LNC-DHA, MLNC-DHA and MLNC-DHA-a1 at  $0.75 \times 10^{11}$  /mL, and also incubated without any nanocapsules (NT). Scale bar: 15 µm.

Given the higher proportion of polyunsaturated fatty acids in oral DHA supplementation, it was expected to potentially increase oxidative stress. However, in our model, no difference was observed in MDA concentration ( $p = 0.47$ ) in the liver homogenate (Fig. 36). The other biomarkers measured in the groups at the end of 32 weeks did not show a significant difference (Table 2). In the subsequent analysis, a LNC-MCT group was included as a control of the MLNC-DHA-a1 group. The LNC-MCT group contained MCT instead of DHA in the lipid core. The effect of the intervention with the nanocapsules and oral supplementation on

systemic cytokines is shown in Fig. 5. The MLNC-DHA-a1 group increased levels of IL-6 (Fig. 5A;  $p < 0.01$ ), IL-1 $\beta$  (Fig. 5B;  $p = 0.01$ ) but also increased IL-10 (Fig. 5C;  $p < 0.01$ ) without altering TNF $\alpha$  (Fig. 5D;  $p = 0.11$ ). No changes were observed in the cytokines determined in the liver (Table 2).

### 3.2.1. Discussion

Our data showed that lipid-core nanocapsules containing DHA (LNC-DHA), multi-wall nanocapsules containing DHA (MLNC-DHA) and the surface-functionalized (anti-PECAM-1) metal-complex multi-wall nanocapsules containing DHA (MLNC-DHA-a1) did not present toxicity when evaluated at 0.14 and 0.75 and  $1.40 \times 10^{11}$  nanocapsules/mL in RAW 264.7 cells, after 24, 48 and 72 h. The toxicity and ability to be phagocytosed by immune system cells is a complex subject that depends on many factors, including carrier components, excipients, impurities, therapeutic content, shape, size, elasticity, surface chemistry, and charge [35]. The nanocapsules were composed of polycaprolactone, sorbitan monostearate, zinc acetate, low molecular weight chitosan and polysorbate 80, as previously described (Fig. S1) [23]. These materials have been widely applied to synthesize nanoparticles without reported toxicity, even using animal models [36–38]. Our results confirm that the material applied to build the capsule wall and the anti-PECAM-1 applied on the surface did not affect the cells viability at  $0.75 \times 10^{11}$  nanocapsules/mL. Moreover, the algae oil (DHASCO®, DSM) containing  $35.13 \pm 0.35$  g/100 g of DHA, used to compose the lipid core, was not sterilized or depyrogenated due to its low oxidative stability. Thus, our results showed that although non-sterilized, the algae oil applied in our study can be considered relatively safe to prepare nanocapsules for further *in vivo* animal assays. However, extrapolating from *in vitro* data to *in vivo* behavior should be done cautiously [35].

Concerning phagocytosis and polarization, the shape and size of our nanocapsules may also have contributed to their internalization by RAW 264.7 macrophages. Our nanocapsules showed a spherical shape, with sizes ranging from  $159.12 \pm 1.25$ – $163.50 \pm 5.33$  nm, and all absolute zeta potential values were below 14 mV, regardless of the negative or positive coating [23]. It has been reported that non-spherical and non-electrical charged carriers may circulate longer than similarly sized spheres, cationic or anionic nanoparticles, due to reduced recognition by

**Fig. 4.** Cytokines concentration and polarization in C57BL/6 mouse bone marrow-derived macrophages (BMDM). Assays were performed with dexamethasone (500 ng/mL) (DEXA), MLNC-DHA ( $0.75 \times 10^{11}$  particles/mL), MLNC-DHA-a1 ( $0.75 \times 10^{11}$  particles/mL containing 200  $\mu$ g/mL of Anti-PEGAM-1 and without any treatment (NT) for 48 h. **Fig. 4A:** TNF $\alpha$  (pg/mL);  $p=0.02$ ; **Fig. 4B:** IL-10 (pg/mL);  $p=0.29$ ; **Fig. 4C:** Percentage of F4/80 + CD80 double positive cells (M1), ( $p=0.25$ ) and **Fig. 4D:** Percentage of F4/80 + and CD206 double positive cells (M2), ( $p<0.01$ ). Vertical bars are mean  $\pm$  SEM (NT,  $n=3$ ; DEXA,  $n=2$ ; MLNC-DHA,  $n=6$  and MLNC-DHA-a1,  $n=5$  for cytokines and NT,  $n=5$ ; DEXA,  $n=4$ ; MLNC-DHA,  $n=6$  and MLNC-DHA-a1,  $n=6$  for polarization). Treatments were compared by One-way ANOVA and Tukey HSD or equivalent non parametric Kruskal Wallis analysis.

host defense cells [35,39]. The ability of RAW macrophages to engulf both MLNC-DHA and MLNC-DHA-a1 nanocapsules, as shown in Fig. 3, may result from a balance between their spherical shape associated with non-ionic surface charge. This combination may influence their further *in vivo* application.

In our study using mice-derived BMDM cells, it was not observed any differences in the M1%, as measured using the F4/80 + CD80 marker (Fig. 4C) or in the IL-10 concentration (Fig. 4B), which is typically found in lower levels in M1 phenotype [40,41]. Taking into account the intense M2 polarization showed by MLNC-DHA-a1 (7.04%) compared with NT (0.30%), as measured using F4/80 + CD206 marker (Fig. 4D), followed by the reduced secretion of TNF $\alpha$  (Fig. 4A) observed to both MLNC-DHA and MLNC-DHA-a1, our results suggest that DHA present in the algae oil composing the lipid core of the nanocapsules has the potential to reduce the inflammatory microenvironment and improve macrophage functionality.

Based on these *in vitro* results, the nanocapsules were evaluated using an animal model. A limited number of *in vivo* studies has investigated the biological effects of omega-3 fatty acids-containing nanomaterials in cardiovascular diseases and cancer [20,42] and to the best of our knowledge, none of these studies has applied algae oil in the core of a nanocapsule surface-functionalized with anti-PECAM-1. For this reason, there was any previous information about a safe dose for intervention.

Our data showed  $5.36 \times 10^8$  surface-functionalized (anti-PECAM-1) metal-complex multi-wall nanocapsules containing 12  $\mu$ L DHA/mL were well tolerated by LDL<sup>0/0</sup> mice, since all groups had similar diet intake and body weight gain, without no signs of local inflammation following caudal vein injections. Furthermore, data from fatty acids profile, relative weight and cytokines concentration suggested that our nanocapsules did not accumulate in the liver, causing any inflammatory reaction.

Conversely, MLNC-DHA-a1 nanocapsules promoted a modulation in the cytokine profile in the plasma, suggesting an inflammatory activation due to the increased release of IL-6 and IL-1 $\beta$  (Figs. 5A and 5B). However, there were no change observed in TNF $\alpha$  (Fig. 5C), while an increase was verified to anti-inflammatory IL-10 (Fig. 5C). It is important to note that several aspects of the nanocarriers can interact with the immune system, remembering that host defenses are the leading causes of nanocarriers side effects [35,43]. It has been reported that the size between 100 and 200 nm has the highest potential for prolonged circulation because this range is large enough to avoid the uptake by the liver, but small enough to avoid filtration in the spleen, thereby extending circulation and providing more opportunities for target engagement [43]. In a study reported by Deshpande et al. [44] flaxseed oil containing 17- $\beta$ -estradiol was nanoencapsulated and functionalized with CREKA-peptides due to their specific binding affinity to

<sup>a</sup> Values were expressed as mean ± SEM (CONT, n = 11; DHA-D, n = 9; LNC-MCT, n = 14 and MLNC-DHA- $\alpha$ 1, n = 15). Treatments were compared by One-way ANOVA and Tukey HSD or equivalent non parametric Kruskal Wallis analysis. P values refer to the comparison among the four groups.

atherosclerotic plaque. Similar to our protocol, the nanocapsules were intravenously injected in ApoE<sup>-/-</sup> mice fed a high-fat diet for 10 weeks, totalizing 10 doses at the end of the experiment. The authors observed that the weight gain of animals was not affected by the treatment, and plasma ALT and AST concentrations remained within the normal range. Sha et al. [42] developed a nanoparticle derived from macrophage membrane-coated liposome, aiming to improve efferocytosis in the arterial wall. They observed good compatibility, prolonged blood circulation time, and no cytotoxicity in MTT assays. Thus, the observed weight gain and dietary tolerance in our study may be attributed to a combination of MLNC-DHA- $\alpha$ 1 size (164 nm), spherical shape and an adequate dose.

Under normal circumstances, opsonization by immunoglobulins and complement proteins begins immediately upon contact of the nanoparticles with plasma, followed by mechanical filtration in the spleen [43]. Although there is no data about pharmacokinetic and pharmacodynamics properties in our research, it is plausible that our nanocapsules infiltrated the inflamed endothelium, spleen or other tissue and cells that express PECAM-1 and have triggered the immune response observed in plasma.

The systemic inflammation observed in our study may be caused by the purity of algae oil in the lipid core, the antibody in the nanocapsule surface or the chitosan applied in the wall, since group LNC-MCT did not show the same behavior. In fact, LNC-MCT group was included in our protocol because there were previous studies reporting its safety when applied in animal models [38,45]. Platelet-Endothelial Cell Adhesion Molecule-1 (PECAM-1) is a protein widely expressed, to different degrees, on most leukocyte subtypes, platelets and endothelial cells, where its expression is primarily concentrated at junctions between adjacent cells [46]. It has been reported that under an inflammatory condition, such as those observed in atherosclerosis, PECAM-1 increases the junction permeability between the endothelial cells, facilitating the infiltration of immune cells into the inflamed intima [47]. However, the toxicity of anti-PECAM-1 has shown controversial results. Fig. 2 shows that 200  $\mu$ g/mL of Anti-PECAM-1 did not reduce viability when evaluated in RAW 264.7 cells. In another study, PECAM-targeted polymer nanocarriers injected into mice did not show toxicity [48]. Despite this, it was observed a systemic release of pro-inflammatory cytokines after intravenous administration of anti-PECAM-1 [49]. This adverse result could be attributed to the fact that the engagement of the extracellular domains of PECAM-1 can compromise barrier function or lead to bidirectional signaling, with consequences toward cell survival, affecting junctional integrity and leukocytes and platelet adhesion. Thus, more studies involving anti-PECAM must be carried out to establish PECAM-1 targeted drugs safety, considering that nanoparticle binding can lead to unexpected biological consequences.

Conversely, chitosan has been considered non-toxic, biocompatible and biodegradable. However, caution should be taken regarding its interactions with biological systems, which depends on concentration, deacetylation degree and positive charge [50]. In a study involving algae oil, two samples obtained from Schizochytrium sp, were submitted to a battery of in vivo and in vitro genotoxicity tests. The results indicated that the oil was well tolerated and had no adverse effects at the highest dose of 3305 and 3679 mg/kg bw/day, for male and female rats, respectively [51], that is about 120 times higher than the dose applied in our study. According to the supplier, the algae oil applied in our nanocapsules contained DHA in the form of triacylglycerol along with ascorbyl palmitate (250 ppm) and tocopherol (250 ppm), being certified as safe for the intended use. However, considering the direct intravenous injection, a higher degree of purity than those approved for dietary use should be evaluated in further studies. Besides the purity, the amount of DHA injected in the plasma by the nanocapsules could trigger an immune system response. In our study, fatty acids were expressed as a percentage, and the proportion found in plasma similar to the proportion found in liver. It was estimated that each application of the nanocapsules provided about 2.8  $\mu$ g DHA kg bw. Thus, quantitative

Fig. 5. Cytokines concentration analyzed in plasma. Fig. 5A: IL-6 concentration (pg/mL); Fig. 5B: IL-1 $\beta$  concentration (pg/mL); Fig. 5C: IL-10 concentration (pg/mL); and Fig. 5D: TNF $\alpha$  concentration (pg/mL). Vertical bars are mean  $\pm$  SEM (CONT, n = 10; DHA, n = 8; LNC-MCT, n = 14 and MLNC-DHA- $\alpha$ 1, n = 12). Treatments were compared by One-way ANOVA and Tukey HSD or equivalent non parametric Kruskal Wallis analysis.

determination of DHA in plasma should be done in the next studies.

Concerning the oral supplementation of algae oil, it was also expected that the replacement of AA by EPA and DHA in membrane phospholipids could promote a reduction in the substrate necessary to synthesize series 2 and 4 eicosanoids, able to facilitate acquired immunity and induce long-lasting immune inflammation [52]. However, there was no difference in cytokines concentration comparing DHA-D and CONT groups, suggesting that the supplementation was insufficient to reduce systemic inflammation once the stimulus was discontinued. Toko et al. [53] observed a suppression in the expression of pro-inflammatory cytokines in the heart of mice supplemented with EPA and DHA. However, it is also worth noting that they applied a dose much higher (1500.00 mg/kg. bw/day) than the dose used in our model (10.00 mg/kg.bw/day). In other study, C57BL/6 mice were supplemented with 200 mg/kg.bw of algae oil and intestinal damage was induced by Ceftriaxone sodium. After 8 days, the animals showed inhibition of the pro-inflammatory cytokine tumor necrosis factor (TNF)- $\alpha$ , interleukin (IL)- 6 and myeloperoxidase (MPO) activity [54]. Xu et al. [55] induced colitis in Male C57BL/6 mice using 2.5% DSS and followed them with 2 weeks of treatment with algal oil (250 or

500 mg/kg/day). The authors concluded that algal oil could be applied in the development of therapeutics for intestinal inflammation.

In fact, there is currently no evidence to suggest that the control of chronic inflammation is dose-related [56]. The solution applied in our study contained  $1.34 \times 10^{13}$  nanocapsules/mL with 12  $\mu$ L/mL of algae oil ( $35.13 \pm 0.35\%$  DHA). This solution was injected at a rate of 40  $\mu$ L/animal once a week for 8 weeks. This amount corresponded to  $8.9 \times 10^{-19}$  mols/animal/week, based on the Avogadro's number. The results showed that MLNC-DHA- $\alpha$ 1 nanocapsules were well-tolerated *in vivo*, but activated an immune response, increasing the cytokines concentration in the plasma. Considering that this immune response is a limitation to clinical trials, future experiments should aim to identify which compound within the nanocapsules was responsible for activating the immune response.

#### 4. Conclusion

Our findings suggest that algae oil with a higher DHA content, incorporated as part of the lipid core within the nanocapsules, appears to improve the macrophage phenotype, being a potential therapy for

controlling chronic inflammation. However, MLNC-DHA-al nanocapsules increased pro-inflammatory cytokines in the plasma. Thus, further studies should identify which compounds triggered the immune response and to assess whether this effect might have adverse implications for susceptibility to infections.

#### Ethics approval and Informed consent

All the protocols were approved by the Institutional Animal Care and Use Committee of the Faculty of Pharmaceutical Sciences, University of São Paulo (CEUA/FCF 555).

**Abstract:** Annexin A1 (AnxA1) is highly secreted by neutrophils and binds to formyl peptide receptors (FPRs) to trigger anti-inflammatory effects and efferocytosis. AnxA1 is also expressed in the tumor microenvironment, being mainly attributed to cancer cells. As recruited neutrophils are player cells at the tumor sites, the role of neutrophil-derived AnxA1 in lung melanoma metastasis was investigated here. Melanoma cells and neutrophils expressing AnxA1 were detected in biopsies from primary melanoma patients, which also presented higher levels of serum AnxA1 and augmented neutrophil-lymphocyte ratio (NLR) in the blood. Lung melanoma metastatic mice (C57BL/6; i.v. injected B16F10 cells) showed neutrophilia, elevated AnxA1 serum levels, and higher labeling for AnxA1 in neutrophils than in tumor cells at the lungs with metastasis. Peritoneal neutrophils collected from naïve mice were co-cultured with B16F10 cells or employed to obtain neutrophil-conditioned medium (NCM; 18 h incubation). B16F10 cells co-cultured with neutrophils or with NCM presented higher invasion, which was abolished if B16F10 cells were previously incubated with FPR antagonists or co-cultured with AnxA1 knockout (AnxA1<sup>-/-</sup>) neutrophils. The depletion of peripheral neutrophils during lung melanoma metastasis development (anti-Gr1; i.p. every 48 h for 21 days) reduced the number of metastases and AnxA1 serum levels in mice. Our findings show that AnxA1 secreted by neutrophils favors melanoma metastasis evolution via FPR pathways, addressing AnxA1 as a potential biomarker for the detection or progression of melanoma.

**Keywords:** neutrophil-depleted mice; melanoma patients; FPR antagonists; B16F10 cells; neutrophil-lymphocyte ratio (NLR)

### 1. Introduction

The tumor microenvironment consists of a heterogeneous population of cancer cells and a variety of other cells including the resident and infiltrating host cells [1]. Infiltrating immune cells in the microenvironment distinctly influences the tumor progression. While T-cell-mediated anti-tumor immune response correlates with favorable disease outcomes and is the basis of cancer immunotherapy [2–5], the myeloid cells act as antigen-presenting cells to promote anti-tumor T-cell responses at the initial phases of tumorigenesis; however, lately, they have been effectors of the tumor progression [6–8].

Neutrophils are myeloid cells constantly produced in the bone marrow and released into the blood. During the host defense against aggressions, this pattern is exacerbated, leading to different neutrophil phenotypes with different half-lives and functions [9,10]. Neutrophilia is also detected in cancer patients, especially those with advanced-stage disease [11], and a high neutrophil-lymphocyte ratio (NLR) has been considered a biomarker of poor clinical outcomes in many types of cancer [12–15]. Neutrophils also represent a significant proportion of immune cells infiltrating in many types of cancer [16–18]. At the tumor site, tumor-associated neutrophils (TAN) are plastic cells that adapt to different microenvironments. In the early tumorigenesis phase, the N1 TAN phenotype stimulates antitumor immune response; however, under the continuous action of chemical mediators released in the tumor microenvironment, TAN changes to a N2 immunosuppressive phenotype and stimulates motility, migration, and invasion of tumor cells [19,20].

In melanoma, the most aggressive type of skin cancer, a body of research has emerged employing NLR in the prognostic of both localized and metastatic melanoma [21–25], as in immunotherapy monitoring in melanoma, being high in NLR was associated with poor outcomes [22,26]. It has been pointed out that circulating neutrophils stimulate angiogenesis and enhanced melanoma cell migration toward blood endothelial cells [27], allowing tumor cell invasion; TLR-4 activation in peripheral neutrophils promotes the metastatic spread of melanoma [28]; and neutrophils activated by complement-membrane-attack-complex release neutrophil extracellular traps (NETs), which open the endothelial barrier favoring melanoma cells to reach into the circulation and their systemic spread [29]. Furthermore, circulating neutrophils migrate to the tumor by actions of chemotactic mediators produced in the lung melanoma microenvironment [30–32], and immature neutrophils at the tumor-bearing lungs display pro-tumoral effects, such as the enhanced frequency of ROS-producing cells [33] and NET formation [34]; conversely, neutrophils expressing lower amounts of Wip-1, a negative regulator of p53, trigger anti-tumor effects [35], and high infiltration of phagocytosing neutrophils evoked by intratumoral injection of vaccine-stimulating biodegradable polysaccharide favors the maturation of dendritic cells and the generation of immune memory [36].

Azurophil granules of neutrophils stock the anti-inflammatory protein Annexin A1 (AnxA1), and in inflammatory conditions, newly synthesized and AnxA1 stored in the neutrophil granules are released into the microenvironment, mainly in microvesicle contents [37]. Secreted AnxA1 is phosphorylated in a calcium-dependent manner and binds to G-protein-coupled receptors named formyl peptide receptors—FPR1 and FPR2—to downstream different intracellular signaling pathways [38,39]. The neutrophil AnxA1 actions are associated with the blockade of leukocyte migration activated at the early inflammation, efferocytosis, and tissue repair [40–42]. Moreover, a lower frequency of circulating neutrophil-AnxA1<sup>+</sup> is associated with a reduction of the plasma levels of the protein, which is found in systemic inflammatory diseases [43], and impaired AnxA1 expression in neutrophils at the site of lesion exacerbates and lengthens the course of inflammation [44].

Many types of cancer cells also express AnxA1, and its effects are associated with cancer development by inducing proliferation, angiogenesis, stemness, and cell invasion in FPR-dependent pathways [45]. Previous studies demonstrated that melanoma cells expressed AnxA1 into the microenvironment, which is associated with angiogenesis, tumor cell invasiveness, and growth [46–48]. *In vitro* studies corroborating the expression of AnxA1 by melanoma cells is related to invasiveness behavior, depending, at least in part, on metalloproteinase-2 (MMP-2) expression [48]. The fine-tuned understanding of neutrophils on solid tumors is nowadays a remarkable goal to clarify the mechanisms of tumor progression and to point out a target for treatment. Hence, we here depicted the role of AnxA1 secreted by neutrophils in lung melanoma mice and melanoma patients and unveiled the fact that AnxA1 derived from the blood or tumor-site neutrophils displays pro-tumor invasiveness during lung melanoma development.

## 2. Materials and Methods

### 2.1. Patients

Eighteen-year-old or older patients with histological confirmation of nevus or melanoma by a pathologist were eligible for enrollment in the study. The patients recruited at A.C. Camargo Cancer Center, São Paulo, Brazil, donated blood (8 mL) and authorized access to biopsies for posterior analysis. Healthy donors were included as controls. The study was conducted under the Declaration of Helsinki and approved by the Ethics in Research Committee of the University of São Paulo and A.C. Camargo Cancer Center (CAAE 277951120.0000.0067 and 277951120.4.3001.5432, respectively). In total, 16 patients were included, and sample characteristics are depicted in Table 1.

Table 1. Characteristics of patient's sample. \*\*\*: absence. SLN: sentinel lymph node.

Characteristics								
Total Patients Enrolled (n) = 16								
Age (Years) (Mean ± SD) = 55.93 ± 15.25								
Patients	Skin Phototype	Site	Diagnostic	Breslow Thickness (mm)	Ulceration	Inflammatory Infiltrate	SLN	Stage
1	I	Left infra scapular	Melanoma	0.6	No	Slight	No	IA
2	NA	Left abdomen	Melanoma	14	No	Discrete	Yes	IV
3	NA	Right leg	Melanoma	0.6	No	Mild	No	IA

### 2.2. Animals

Female C57BL/6 mice wild-type (AnxA1<sup>+/+</sup>) or AnxA1-knockout mice (AnxA1<sup>-/-</sup>) (25–30 g; 3–5 per group) were provided by the Central Animal House of the School of Pharmaceutical Sciences and the Chemistry Institute of the University of São Paulo. Mice were housed in polycarbonate cages (four animals per cage; Tecniplast, Buguggiate, Italy) at room temperature (22 °C ± 0.1 °C) and humidity (50% ± 10%) with a 12 h light/dark cycle, receiving standard food and water ad libitum. Animals were anesthetized with a combination of ketamine/xylazine solution (20:2 mg/kg, intraperitoneal (i.p.); xylazine

hydrochloride—Ceva Santé Animale; ketamine—Syntec do Brasil Ltda) before each experimental procedure. All procedures were approved by the Institutional Animal Care and Use Committee (IACUC) at the School of Pharmaceutical (CEUA FCF/USP 583).

### 2.3. Melanoma Cell Culture

The B16F10 malignant melanoma cell line was obtained from the Banco Células do Rio de Janeiro (BCRJ), Rio de Janeiro, Rio de Janeiro, Brazil. Cells were grown in culture dishes for 5–10 passages in Dulbecco's modified Eagle's medium (DMEM; #12100046 Gibco, Carlsbad, CA, USA) supplemented with 10% heat-inactivated fetal bovine serum (FBS; #2024-06 Gibco) and 100 U/mL penicillin and 100 µg/mL streptomycin solution (#15140-122 Gibco), maintained at 37 °C with 5% CO<sub>2</sub> atmosphere. Reverse transcription polymerase chain reaction (RT-PCR) was performed routinely in the laboratory to check the mycoplasma cell contamination. AnxA1 and FPR expression in melanoma cells were evaluated by flow cytometer as described below.

### 2.4. Collection of Plasma and Isolation of Blood Human Neutrophils

An aliquot of fresh and heparinized venous blood from patients and control donors was used to total leukocyte and smear blood count. The count of total leukocytes was performed using a Neubauer chamber, and smear blood was stained with Giemsa to circulating leukocyte differentiation. The NLR was calculated by the ratio between the number of circulating neutrophils and lymphocytes counted. Plasma was separated by centrifugation, recovered, and stored at −80 °C until AnxA1 serum levels measurement. Afterward, erythrocytes and leukocytes pellet were diluted in 0.9% NaCl, and neutrophil isolation was carried out by density gradient centrifugation, as described previously [49]. Isolated neutrophils were fixed and analyzed by flow cytometer as described in the following item.

### 2.5. Collection and Culture of Mice Neutrophils

Neutrophils were obtained from wild-type and AnxA1<sup>−/−</sup> mice, 4 h after intraperitoneal injection of 3 mL 1% oyster glycogen Type II solution (#G8751 Sigma-Aldrich, Saint Louis, MO, USA), previously prepared in phosphate-buffered saline (PBS) [50]. The animals were anesthetized, and the cells were collected by rinsing the abdominal cavity with 10 mL of PBS. To macrophage adherence, peritoneal cells were incubated for 2 h in DMEM supplemented with 10% FBS, 100 U/mL penicillin, and 100 µg/mL streptomycin. Afterward, non-adhered neutrophils were recovered and counted in the Neubauer chamber. Then, neutrophils ( $1 \times 10^6$ ) were seeded in a 96-well plate (Corning, New York, NY, USA) and cultured in DMEM supplemented with 10% FBS for 18 h. After culture, the cell-free supernatant was recovered as Neutrophil Conditioned Medium (NCM), filtered through a 45 µm filter (Corning), stored at −80 °C, and used according to assays. The purity of the peritoneal cell population and viability were analyzed by flow cytometry.

### 2.6. Induction of Melanoma Lung Metastasis in Mice

Cultured B16F10 cells were harvested, washed, and resuspended to give the appropriate concentration in serum-free DMEM. B16F10 cells suspension ( $5 \times 10^5$  cells/100 µL) was injected into the mice via the tail vein [51]. The animals were maintained under observation, and after 21 days of tumor cell injection, the mice were submitted to euthanasia by overexposure to nasal anesthesia (isoflurane; 2-chloro-2-(difluoromethoxy)-1,1,1-trifluoroethane; Cristália, Brazil). For neutrophil depletion, 150 µg anti-Gr1 (16-5931-95; clone RB6-8C5 Bioscience/Invitrogen, Waltham, MA, USA) or rat IgG2b kappa isotype (#14-4031-85 Bioscience/Invitrogen) were injected 24 h before melanoma cell inoculation. The antibodies were injected every 48 h for up to 21 days. The blood was recovered from aorta vein to obtain the plasma and circulating leukocytes for posterior analysis. The lung was recovered and perfused, and the number of B16F10 metastases was counted by visual inspection helped with stereo microscopy (CL 6000 LED, Zeiss, Oberkochen, Germany), followed by fixation.

### 2.7. Histology of Human Biopsies and Mice Lungs

Mice and human biopsies were fixed in 4% buffered paraformaldehyde, dehydrated and embedded in paraffin. Slides sections (4  $\mu$ m) were dewaxed with xylene and rehydrated through gradient ethanol into water. Hydrated slides were stained with hematoxylin/eosin (H&E EasyPath, São Paulo, Brazil) for morphological analyses or used for immunofluorescence or immunohistochemistry assays.

### 2.8. Immunofluorescence

The immunofluorescence was performed according to Zaqout et al. (2020) [52]. Briefly, for antigen retrieval, sections were heated in citrate buffer (pH 6.0) for 40 min at 95 °C in a water bath. After cooling at room temperature, the sections were rinsed and permeabilized with 0.2% gelatin from cold water fish skin (#G7041 Sigma Aldrich) and 0.25% Triton-X-100 (#X100 Sigma-Aldrich) in PBS. Sections were blocked with 5% bovine serum albumin (BSA; #A7030 Sigma Aldrich), 0.2% gelatin, and 0.25% Triton-X-100 in PBS. Patients' samples were incubated with anti-AnxA1 mouse antibody (1:50; #610066 BD Biosciences, San Jose, CA, USA) overnight (4 °C), followed by incubation with anti-mouse Alexa Fluor 488 (1:250; #10680 Invitrogen). Lung sections were processed as mentioned previously and incubated with anti-rat Ly6G (1:25; clone 1A8—#16-9668-82 Bioscience/Invitrogen) and anti-AnxA1 rabbit antibody (1:50; #71-3400 Invitrogen). Afterwards, samples were incubated with anti-rat-Alexa-Fluor 488 (1:250; #A1106 Invitrogen) and anti-rabbit Alexa Fluor 568 (1:100; A11001 Invitrogen). The nuclei were stained with DAPI (1  $\mu$ g/mL; #554907 BD Bioscience). Negative controls were obtained by omitting the primary antibody. Immunofluorescence was analyzed using an Axioskop 2 fluorescence microscope (Carl Zeiss, Jena, Germany), and images were captured using the software AxioVision 4.7 (Carl Zeiss). The Ly6G<sup>+</sup>-positive cell count was performed using the cell counter tool from Fiji/ImageJ software (Version 2.9.0/1.53t National Institutes of Health, Bethesda, MD, USA). Five fields were analyzed from each lung section. The analysis of AnxA1 expression in Ly6G<sup>+</sup>-positive cells was performed according to de Paula-Silva and collaborators [53]. Briefly, composite pictures (czi format) were imported to Fiji from ImageJ and split into blue and green or red channels. For densitometric analysis, the green or red channel was selected, further analyzed, and modified in the gray filter. Background pixel averages were then subtracted from the image pixels of interest to correct uneven illumination. Fluorescence measures were performed manually by the selection of positive regions; average values were expressed in arbitrary units.

### 2.9. Immunohistochemistry

After antigen retrieval and permeabilization with 0.1% Triton-X-100 in PBS, peroxidase was inactivated with 3% hydrogen peroxide (Synth, Diadema, Brazil), and nonspecific antibody binding was blocked by preincubating sections with 10% BSA in PBS at 37 °C for 60 min. Sections were incubated with diluted primary antibodies against melanoma marker Melan A (1:50; #PA5-99174 Invitrogen) or AnxA1 (1:500, #713400 Thermo Fisher) at 4 °C overnight. Then, slices were washed and incubated with HRP-conjugated anti-rabbit (#ab6721 Abcam, Cambridge, UK) at room temperature for 1 h. The sections were developed with 3,3'-diaminobenzidine (DAB; #K3468 Dako, Carpinteria, CA, USA) and lightly counterstained with hematoxylin (Merck, Darmstadt, Germany), followed by dehydration and coverslip mounting. Negative controls were performed by omitting the primary antibody.

### 2.10. Serum and Ccl Supernatant AnxA1 Measurement

The levels of AnxA1 in human and mouse blood and in the neutrophil-conditioned medium were quantified by ELISA using commercial kits (human: #MBS495574; mouse: #M704042, MyBioSource, San Diego, CA, USA) according to supplier instructions.

### 2.11. Flow Cytometry

Flow cytometry experiments were performed to characterize the expression of AnxA1, FPR1, FPR2, CD66b, Ly6G, and F4/80. To evaluate the expression of AnxA1 and CD66b

in human neutrophils, isolated cells were fixed with FACS lysing solution (#349202 BD Biosciences), washed with PBS containing 0.1M glycine (Synth), permeabilized with 0.01% Triton-X-100, washed with 1% BSA in PBS (BSA/PBS), and incubated with primary anti-rabbit antibody to AnxA1 (1:100) for 1 h at 37 °C. Next, cells were washed with BSA/PBS and incubated with secondary goat anti-rabbit antibody conjugated to Alexa Fluor 488 (1:250; Invitrogen) and anti-PerCP-Cy<sup>TM</sup>5.5 anti-human CD66b-neutrophil marker (1:50; #562254 BD Pharmingen) for 40 min in the dark at room temperature. To verify the frequency of mice circulating neutrophils (Ly6G<sup>+</sup>) and monocytes (F4/80<sup>+</sup>), cells were fixed with FACS lysing solution for 30 min at room temperature, washed with PBS containing 0.1M glycine, and incubated with anti-Ly6G conjugated with FITC (1:50; #551460 BD Pharmingen) and anti-F4/80 conjugated with PerCP-Cy5.5 (1:200; # 15-4801-82 Biolegend, San Diego, CA, USA) for 40 min in the dark at room temperature. The cells were analyzed by a flow cytometer (BD Accuri C6), taking 10,000 events into consideration and using BD CSampler<sup>TM</sup> Analysis software (version: 1.0.2641-21 BD Biosciences, Franklin Lakes, NJ, USA).

### 2.12. Transwell Matrigel Invasion Assay

Transwell membranes (8 µm pore size; #353097 Falcon/Corning) were coated with 40 µL Matrigel (#356237 Corning diluted 1:6 in serum-free DMEM). B16F10 melanoma cells ( $2.0 \times 10^4$  cells/transwell) were resuspended in DMEM supplemented with 0.5% BSA and added to the inner compartment of the chamber [54]. One set of experiments was performed to investigate the role of the neutrophil-conditioned medium (NCM; supernatant from 18 h neutrophils cultured obtained from wild-type or AnxA1<sup>-/-</sup> mice) on melanoma cell invasion. Hence NCM:DMEM 5% FBS culture medium (300 µL; 1:1 dilution) or DMEM 5% FBS (Control) were added to the outer cup. Another set of experiments investigated the role of the contact of neutrophil–melanoma cells on invasion. In this case, neutrophils (obtained from wild-type or AnxA1<sup>-/-</sup> mice) and melanoma cells were co-cultured in a proportion of 5:1 for 24 h. The participation of FPRs on the effects was evaluated by treatment of melanoma cells with FPRs antagonists, cyclosporine H (1 µM; #AG CN2 0447-M005 Adipo Gen Life Sciences, San Diego, CA, USA), or WRW4 (1 µM; #2262 Tocris Bioscience, Bristol, UK) for 30 min and before adding to the inner compartment of the chamber. To confirm the involvement of AnxA1, NCM with low amounts of AnxA1 or AnxA1<sup>-/-</sup> NCM were supplemented with recombinant AnxA1 (1.5 and 3.5 ng/mL; donated by Professor Chris Reutelingsperger from Cardiovascular Research Institute Maastricht, Maastricht University, Maastricht, The Netherlands). After 24 h, cells that migrated through the Matrigel were fixed in 1.0% glutaraldehyde solution (#354400 Sigma Aldrich) and stained with 0.5% toluidine blue in 2% of Na<sub>2</sub>CO<sub>3</sub> (Synth) for 20 min. The number of migrated cells was counted under a Leica DM11 inverted microscope (Leica, Shinagawa, Tokyo, Japan). In each well, seven independent fields were considered for quantitation. The data are represented as change fold in relation to control or total number of invading cells.

### 2.13. Statistical Analysis

Statistical analyses were performed using Graph Pad Prism4 (Graph Pad Software Inc., San Diego, CA, USA). The data were expressed as mean ± standard error of the mean (SEM), and comparisons were made between the experimental groups using the *t*-test or one-way ANOVA followed by Tukey's post hoc test for multiple comparisons using GraphPad software version 5 (San Diego, CA, USA). The level of significance was set at  $p < 0.05$ .

## 3. Results

### 3.1. Expression and Serum AnxA1 Levels Were Increased in Melanoma Patients

The samples included were obtained from nevus or melanoma patients with different Breslow index and stages, or *in situ* melanoma (Table 1). The inflammatory infiltrate was classified as mild to severe, represented mainly by lymphocytes identified by morphological characteristics (Figure 1A–C—black arrows and inserts). AnxA1 expression was verified in four biopsy specimens (dysplastic nevus = 1; melanoma = 3). The selected melanoma

samples showed Breslow indexes around 0.8 mm (Figure 2F), 1.1 mm (Figure 2H), and 3.2 mm (Figure 2J). As observed by H&E staining, the samples showed pigmented cells (\*) and melanoma cells (black arrow) characterized as large and rounded cells with large nuclei (Figure 1D,E,H,J). In the dysplastic nevus and first melanoma samples, cells scattered throughout the dermis, as seen by H&E staining (Figure 1D,F), were positive for AnxA1 in both samples (Figure 1E,G). In the second melanoma sample, an increased number of pigmented and melanoma cells (Figure 1H) and AnxA1-positive cells (Figure 1I) were detected. In the third sample, the majority of cell types found in the dermis were melanoma cells (Figure 1J), being that almost all of them expressed AnxA1 (Figure 1K). Peripheral blood was also analyzed. Patients with melanoma showed an increased circulating neutrophil compared to the nevus (Figure 1L). In melanoma patients, the NLR was around 2.5, while in nevus patients, the NLR was 1.69. Furthermore, a high expression of AnxA1 was found in circulating neutrophils (CD66b positive cells) from melanoma patients compared to nevus patients and the control (Figure 1M), and serum AnxA1 levels were increased in patients with melanoma (Figure 1N).

### 3.2. Neutrophils Were AnxA1<sup>+</sup> in The Lung Melanoma Metastasis Model

On the basis of the expression of AnxA1 in melanoma cells and neutrophils from melanoma patients, a model of lung melanoma metastasis was employed to investigate the pattern of AnxA1 expression and neutrophil infiltration in the metastatic site. As shown in Figure 2A, lung metastasis was observed 21 days after i.v. injection of B16F10. In the lungs of control animals, AnxA1 labeling was detected in the alveolar (arrowheads) but not in the bronchiolar epithelium (Br—Figure 2B,C). Conversely, the lung melanoma metastasis was composed of AnxA1<sup>+</sup> tumor cells (T—Figure 2D,E) and immune cells (arrows—Figure 2F,G). As verified by Ly6G-neutrophil marker labeling (Figure 2H,I), the number of neutrophils increased in the melanoma group (Figure 2J). Furthermore, Ly6G and AnxA1 double labeling (Figure 2K) or AnxA1 melanoma labeled cells (Figure 2L) showed that neutrophils expressed higher amounts of AnxA1 than melanoma cells (Figure 2M).

### 3.3. Peripheral Blood Neutrophils and AnxA1 Levels Were Enhanced in the Lung Melanoma Metastasis Model

The number of circulating neutrophils was elevated in melanoma metastasis mice in comparison to that found in the control group (Figure 3A). Moreover, levels of AnxA1 in the serum were augmented in lung melanoma metastasis mice (Figure 3B). To verify the ability of neutrophils to secrete AnxA1, peritoneal neutrophils were collected from naive mice, and greater amounts of AnxA1 release were found in the supernatant from these cells than B16F10 cells when cultured for 24 h (Figure 3C).

**Figure 1.** Expression and serum levels of AnxA1 were increased in melanoma patient samples. #### 3.4. AnxA1 Secreted by Neutrophils Increased the Melanoma Cell Invasion via FPRs Pathways

On the basis of these previous data, we further investigated the involvement of AnxA1 secreted by neutrophils on melanoma cell invasion. Thus, neutrophils were recovered from the peritoneal cavity as depicted in Supplementary Figure S1A. Almost 80% of the total peritoneal cells were neutrophils, and 20% were macrophages as observed by Ly6G and F4/80 labeling, respectively (Supplementary Figure S1B). After macrophage removal by plated-adherence for 2 h, neutrophils were incubated for 18 h, and viability was reduced with an increase in Annexin V, an apoptosis marker (Supplementary Figure S1C), which was expected, since neutrophils' life span during *in vitro* incubation is around 7 to 10 h for both human and mice cells [55,56]. Furthermore, the levels of AnxA1 secreted by the neutrophil supernatant, named neutrophil-conditioned medium (NCM), was 2 up to 8 ng/mL (Supplementary Figure S1D). Considering that AnxA1 effects are attributed to its cleaved form, NCM was analyzed by Western blotting. As shown in Supplementary Figure S1E, the AnxA1 found in the NCM was cleaved. On the basis of the concentration of AnxA1, NCM was divided into high and low AnxA1 content and employed to investigate the invasion of melanoma cells. For this, murine melanoma B16F10 cells were applied, in which AnxA1 and its receptors (FPR1 and FPR2) were first characterized (Supplementary Figure S2A). B16F10 cells were incubated with NCM, at a proportion of 1:1, with a standard culture medium (DMEM supplemented with 5% FBS) or with standard medium (control) for 24 h (Figure 4A). In the assayed conditions, high AnxA1 content NCM increased the melanoma cell invasion in comparison to the control (Figure 4B), which was not associated with increased cell proliferation (Supplementary Figure S2B). To evaluate the involvement of AnxA1 in the effect promoted by NCM, melanoma cells were pre-treated with cyclosporine (CsH) or WRW4, antagonists for FPR1 and FPR2, respectively. As observed in Figure 4B, incubation with the antagonists reduced the melanoma cell invasion, which was not due to alterations in the cell viability (Supplementary Figure S2C). Further,

in NCM containing low levels of AnxA1 (lower than 2 ng/mL), the melanoma cell invasion was reduced in comparison to NCM with detectable AnxA1 levels. The addition of rAnxA1 to non-detectable AnxA1 NCM recovered the cell invasion previously observed (Figure 4C). The role of AnxA1 on cell invasion was corroborated using NCM from neutrophils collected from AnxA1 knockout mice (*AnxA1*<sup>-/-</sup>). In this condition, the melanoma cell invasion was reduced, which was rescued by the addition of the rAnxA1 (Figure 4D).

The melanoma cell invasion was also evaluated in B16F10-neutrophil co-culture (Figure 4E). As observed in Figure 4E, neutrophil co-culture enhanced the melanoma cell invasion, which was inhibited if melanoma cells were pre-treated with FPR1 and FPR2 antagonists. The reduction of cell invasiveness was also observed if neutrophils were collected from *AnxA1*<sup>-/-</sup> mice (Figure 4G).

We also investigated whether melanoma-conditioned medium (MCM) could change the neutrophil's phenotype. Indeed, MCM reduced the expression of ICAM-1 at the neutrophil's surface (Supplementary Figure S3A) and increased the secretion of CXCL1, KC, MCP-1, Arginase, VEGF, and IL-10 (Supplementary Figure S3C–E). As this neutrophil's profile is characteristic of the N2 phenotype, it may indicate that neutrophils at the site of metastasis display an anti-inflammatory phenotype.

### 3.5. Depletion of Circulating Neutrophils Reduced Lung Melanoma Metastasis and Serum Levels of AnxA1

Once AnxA1 secreted by neutrophils displayed a role in melanoma metastasis, we further investigated whether depletion of these cells during the disease progression was able to alter the disease outcomes. We depleted circulating neutrophils using anti-granulocyte antibody anti-Gr1 before B16F10 injection until the end of the lung melanoma metastasis model (Figure 5A). In our model, the antibody dosage and schedule reduced the number of peripheral neutrophils during the 48 h period after the antibody injection (Figure 5a). There was no detected modification in the number of circulating monocytes in the blood, while the number of blood neutrophils remained reduced up to day 21 (Supplementary Figure S4A). The remaining neutrophils showed morphology like an immature phenotype (Supplementary Figure S4A'), which may have been the result of bone marrow response to anti-rat antibody production (mitigation), due to limited depletion in peripheral tissue (low bioavailability), or due to the induction of neutrophil production in the spleen (extramedullary granulopoiesis), as discussed by recent literature [57,58].

Even the completed neutrophil depletion was not achieved; we observed a significant reduction of melanoma metastasis spots as observed by macroscopic analysis of the lungs from depleted neutrophils (anti-Gr1 treated) in comparison to the isotype group (Figure 5B–D). Histologic analysis using H&E staining showed that the isotype group had metastasis in the external regions of lobes and near blood vessels (Figure 5E). The lungs of neutrophil-depleted mice showed tumor mass spots near vessels; however, the size was smaller than that found in the isotype group (Figure 5F). Further, we observed an increase in the circulating lymphocytes in the neutrophils depleted animals in comparison to isotype mice (Supplementary Figure S4B–D). Bronchoalveolar lavage (BAL) showed a reduced level of TGF- $\beta$  and VEGF- $\alpha$  (Supplementary Figure S4E,F), which may have been related to the reduced number of neutrophils in the lungs. To characterize lungs from neutrophil-depleted mice, we performed immunohistochemistry analysis using a melanoma marker (Melan A). Thus, it was verified that the Melan A-positive cells were restricted to the tumor (Figure 5G). On the other hand, in neutrophil-depleted mice, Melan A-positive cells were found to be mixed with other Melan A non-labeled cells also near vessels (Figure 5H). It was also observed that Melan A-positive cells were found spreading in the lung tissue of depleted-neutrophil mice (Figure 5H—insert). The AnxA1 expression was found in melanoma tumor cells (Figure 5I,J) and immune cells (Figure 5i,j) in the lung from both isotype and neutrophil-depleted mice. Furthermore, the depletion of neutrophils reduced the levels of serum AnxA1 (Figure 5E), reinforcing the potential of AnxA1 as a melanoma biomarker.

**Figure 4.** Neutrophil-conditioned medium or neutrophil cultured with melanoma cells increased the cell invasion by in a dependent manner of AnxA1. (A) Experimental design. #### 4. Discussion

Neutrophils have been recognized as relevant players in cancer biology. Their actions are under robust investigation as they display anti- or pro-tumoral activities. The duality of neutrophil behavior is dependent on the phase of the disease, tumor environment contents, and the state of neutrophil activation in the blood or tumor sites. AnxA1<sup>+</sup> neutrophils are fundamental to halting inflammation, and although AnxA1 secreted by cancer cells is involved in metastasis development, the role of AnxA1 derived from neutrophils in tumor invasiveness is underestimated. Hence, we addressed this issue, showing AnxA1 secreted by neutrophils contributes to the development of melanoma lung metastasis by promoting cancer invasiveness through FPR1/FPR2 pathways.

The up-expression of AnxA1 by tumor cells takes place in solid tumors of different origins and is associated with poor outcomes [59–62], implicating AnxA1 as a common mediator of cancer development. Indeed, aggressive human melanoma cell lines express high amounts of AnxA1 related to cell invasiveness, as verified by impairing melanoma cell invasion when endogenous AnxA1 protein levels were reduced [46]. Moreover, the treatment of the melanoma cells with the mimetic AnxA1 N-terminal peptide Ac2–26 stimulated the invasiveness by increasing MMP-2 expression, depending on FPR/MAPK/STAT3 activation pathways [46–48]. Furthermore, impaired melanoma lung metastasis in AnxA1<sup>-/-</sup> mice was associated with the inhibition of angiogenesis [63], pointing out that AnxA1 is a player protein such as on cancer stromal cells. A previous retrospective clinical study showed that high AnxA1 expression in melanoma cells from primary tumors reduced metastasis-free survival, but AnxA1 expression levels were unchanged according to the Breslow index [46]. Here, data obtained in melanoma patients corroborate this evidence, as augmented AnxA1 expression in the cytoplasm of cells from a dysplastic nevus and melanoma patients was detected. However, the intensity of AnxA1 labeling did not change according to melanoma cells migrating deeper or spreading into the dermis, suggesting that maintenance of constitutive AnxA1 expression is an effector molecule mediating the tumor progression.

The NLR is a readily available metric with an emerging role in melanoma prognosis [15]. For localized melanoma, a high NLR is predictive of worse overall survival. However, the optimal cut-off for NLR is not established, varying between 2 and 5 [15]. Patients with NLR > 5 had significantly worse median overall survival in comparison with low NLR [64]. Similarly, NLR value has been considered in the prognostic of the patients receiving checkpoint inhibitors [24–26]. For instance, Bartlett et al. (2020) demonstrated that patients from the high-NLR group were more likely to have higher disease burden and poorer overall performance status. Furthermore, an NLR increase of ≥30% after initiation of therapy was also associated with shortened overall survival [65]. Although the number of patients included in our study was small, we observed a peripheral neutrophilia and the NLR was around 2.5, which is within the range considered for localized melanoma. Interestingly, we also observed that blood neutrophils from melanoma samples showed increased AnxA1 expression compared to nevus. The function of circulating AnxA1<sup>+</sup> neutrophils in melanoma is not yet known and deserves further investigation. Nonetheless, AnxA1<sup>+</sup> neutrophils in the blood are related to an immunosuppressive profile [39,41,66,67]. Furthermore, the potential of AnxA1 serum levels as a tumor biomarker has not been well explored. Its upregulation was only associated with pathological grade and clinical stage in patients with lung cancer [68]. Here, high serum AnxA1 levels and neutrophils expressing AnxA1 were consistent, such as that found in melanoma samples from patients as in the melanoma mice model. The fact that we found an increase in AnxA1 serum levels brings an alternative approach to help in the diagnosis of melanoma, and a large cohort is needed to support the potential of AnxA1 as a biomarker for melanoma detection or progression.

Further experimental data showed that neutrophils that infiltrated into the melanoma lung metastasis expressed elevated levels of AnxA1 in comparison to melanoma cells. A broad amount of data show that AnxA1 secreted by neutrophils into the inflammatory environment is phosphorylated and exerts autocrine and paracrine actions to halt the

inflammatory process and to induce efferocytosis [69]. To the best of our knowledge, we suggest, for the first time, that neutrophils secrete AnxA1 in melanoma metastasis and can influence tumor development. Hence, to confirm this hypothesis, an *in vitro* platform was carried out to detect the role of neutrophils or neutrophil-secreted products (NCM) on tumor cell invasiveness. Indeed, such melanoma cells co-cultured with neutrophils as incubated with NCM presented higher invasiveness, which was rescued if neutrophils were obtained from AnxA1<sup>-/-</sup> mice. The antagonisms of FPR1 or FPR2 also inhibited the augmented invasiveness of melanoma cells co-cultured with neutrophils or incubated with NCM. In the conditions where rAnxA1 was added to the medium, the melanoma cell invasion was lower than that found in NCM. Studies have shown that the active form of AnxA1 is associated with the N-terminal region, which can be exposed after a conformational change at the neutrophil plasma membrane or cleaved in a 33 kDa fragment by enzymes as elastase [70,71]. Here, we verified that AnxA1 secreted by neutrophils is cleaved. The lower effect promoted by rAnxA1 in comparison to NCM could be associated with the lack of the cleavage process. Hence, this body of data drives a pivotal role of AnxA1 secreted by neutrophils in melanoma invasion via the FPRs axis.

We here confirmed that B16F10 cells constitutively express FPR1 and FPR2, and data from the literature show that AnxA1 binds to both receptors and leads to cancer progression, such as breast cancer [67]. Interaction of AnxA1 with FPRs modulates signal transduction pathways, such as oncogenic signaling and extracellular-signal-related kinase (ERK) phosphorylation, resulting in cell invasion [72]. Indeed, the MAP kinase pathway is associated with melanoma development, as the inhibition of the members of the RAS-RAF-MEK-ERK axis has been a target of recent drugs to treat melanoma [73]. Moreover, previous studies showed that AnxA1 stimulated MMP-2 activity by interaction with FPRs, increasing cell invasiveness and promoting the proliferation and migration of melanoma cells *in vitro* [48,74].

Nonetheless, we may also suggest that AnxA1 secreted by N2 phenotype neutrophils influences stromal and immune cell behavior in the microenvironment, favoring the tumor progress. Indeed, AnxA1 via FPR1 potentiates the VEGF-A signaling in endothelial cells by promoting new vessel formation [75], and neutrophil-derived AnxA1 is related to angiogenesis during the development of the placenta [43]. Additionally, the reduction of lung melanoma metastasis in AnxA1<sup>-/-</sup> mice was associated with neovascularization impairment [63]. As mentioned before, N2 neutrophil-secreting AnxA1 displays immunoregulatory effects [39,41,66,67], which may effectively contribute to the immunosuppressive status of the metastasis sites. Robust evidences show a complex interplay of chemical mediators secreted by cancer cells and neutrophils on tumor progression when mediators secreted by cancer cells induce the switch of neutrophils to the N2 phenotype [75,76]. A recent report demonstrated that melanoma cell–neutrophil interaction supports cancer progression by priming neutrophils towards a pro-tumor N2 phenotype [77]. Indeed, the data here obtained show that melanoma-conditioned medium polarizes neutrophils into the N2 phenotype.

In addition, we observed a reduction of melanoma metastasis formation and serum levels of AnxA1 in neutrophil-depleted mice. Furthermore, an increase in lymphocytes was detected in lung metastasis, indicating that neutrophils at the tumor site may act as immunosuppressive cells. Indeed, neutrophil depletion has unveiled its role on cancer progression by suppressing antitumor T cells [78]. T-cell activation can be inhibited directly by TGF- $\beta$  or IL-10 secreted by N2 phenotype [19] or indirectly by MMP-9 secretion that activates the TGF- $\beta$  by proteolytic cleavage [79]. Moreover, neutrophils favor melanoma dissemination by releasing the neutrophil extracellular traps (NETs) induced by complement membrane attack complexes; NETs lead to the endothelial barrier opening that allows melanoma cells to enter the circulation and systemic spread [29]. Indeed, lung metastasis induced by melanoma cells expressing AnxA1 is impaired in AnxA1<sup>-/-</sup> mice [63], addressing the fact that constitutive AnxA1 secreted by other mice cells are involved in the metastasis.

Herein, the reduction of neutrophils implied in the serum AnxA1 secretion decrease, which may impair melanoma cell invasion and, consequently, its dissemination.

Our findings added AnxA1 secreted by neutrophils in the blood or at metastasis sites as a new player of the melanoma cell invasion, pointing to AnxA1 as a pivotal mediator secreted by neutrophils acting on cancer cells. These data open a venue for investigations about the mechanisms of AnxA1 secreted by neutrophils, such as in the blood as in tumor metastasis and to propose AnxA1 blood levels or AnxA1<sup>+</sup> neutrophils as a biomarker of early detection or melanoma progression.

21

**22 Abstract**

23 Inflammatory bowel diseases (IBDs) disrupt the intestinal epithelium, leading to severe chronic  
24 inflammation. Current therapies cause adverse effects and are expensive, invasive, and ineffective for most  
25 patients. Annexin A1 (AnxA1) is a pivotal endogenous anti-inflammatory and tissue repair protein in IBD.  
26 Nanostructured compounds loading AnxA1 or its active N-terminal mimetic peptides improve IBD  
27 symptomatology. To further explore their potential as a therapeutic candidate, the AnxA1 N-terminal mimetic  
28 peptide Ac2-26 was incorporated into SBA-15 ordered mesoporous silica and covered with Eudragit® L30-  
29 D55 to deliver it by oral treatment into the inflamed gut. The systems SBA-Ac2-26 developed Measurements  
30 revealed self-assembled rod-shaped particles, likely on the external surface of SBA-15, and 88% of peptide  
31 incorporation. SBA-15 carried the peptide Ac2-26 into cultured Raw 264.7 macrophages and Caco-2  
32 epithelial cells. Moreover, oral administration of Eudragit-SBA-Ac2-26 (200 µg; once a day; for 4 days) to  
33 mice under dextran-sodium sulfate-induced colitis reduced colitis clinical symptoms, inflammation, and  
34 improved epithelium recovery. Our findings demonstrate a simple and cost-effective approach to delivering  
35 Ac2-26 orally into the inflamed gut, highlighting its potential as non-invasive IBD therapy.

36

37 **Keywords:** Annexin A1; SBA-15; oral route; tissue recovery; inflammation.

38

## 39 Introduction

40 The incidence of inflammatory bowel diseases (IBDs) has increased in the past years in developed  
41 and newly industrialized countries. Divided into two distinct types: ulcerative colitis (UC) and Crohn's  
42 disease (CD) are relapsing and chronic inflammatory diseases that mainly affect the large intestine.<sup>1</sup> Both  
43 UC and CD patients present debilitating symptoms like tenesmus, blood stool, diarrhea, and fatigue.<sup>2</sup>  
44 Notably, malignant colorectal cancer, small bowel cancer, intestinal lymphoma, and cholangiocarcinoma  
45 are enhanced in IBD patients; in addition, the high incidence of neoplasms is related to IBD-treated patients,  
46 implicating the adverse effects of available drugs.<sup>3</sup> Besides the considerable weakening situation that  
47 patients with IBD need to confront, around 50% of patients fail or present a loss of effectiveness of available  
48 drugs. Furthermore, the most recent biological treatments are expensive and require invasive  
49 administration. These features pose IBDs as a remarkable public health problem worldwide.<sup>1,4</sup> Hence, the  
50 look for novel biological targets and drugs and pharmaceutical approaches to deliver non-invasive drugs  
51 hallmarks IBDs as a subject in biological and drug development research.<sup>5</sup>

52 Annexin A1 (AnxA1) comprises a 37KDa endogenous protein of the calcium and phospholipid-  
53 binding Annexin superfamily.<sup>6,7</sup> Annexins present a C-terminal and an N-terminal domain; the last domain  
54 is specific for each superfamily component and confers specificity to biological activities.<sup>7</sup> AnxA1 was first  
55 characterized as a glucocorticoid-regulated anti-inflammatory protein,<sup>6,8,9</sup> nowadays, AnxA1 is recognized  
56 as a potent anti-inflammatory and resolvins molecule, being a mediator of cell proliferation, differentiation,  
57 and apoptosis of immune, epithelial, and cancer cells.<sup>10-12</sup> AnxA1 binds to intracellular structures, to  
58 membrane phospholipids, or to G-transmembrane coupled formyl peptide receptors to trigger the  
59 downstream activation of intracellular pathway.<sup>8</sup>

60 Robust evidence has associated the pivotal role of AnxA1 in the control of IBDs; as such, infiltrating  
61 leukocytes and epithelial intestinal cells express the protein during the course of the disease. Absence or  
62 low levels of the protein worsens and maintains the uncontrolled inflammation that perpetuates the  
63 disease.<sup>13-17</sup> AnxA1 interactions with formyl peptide receptor 1 (FPR1) mediate the IBD wound closure, and  
64 formyl peptide receptor 2 (FPR2) evokes mucosal healing by regulating the traffic and functions of  
65 leukocytes into the inflamed tissue.<sup>18-22</sup> Ac2-26 comprises the 25 amino acids of the N-terminal sequence

66 of AnxA1 that binds to FPR1 and 2 to display equivalent biological actions of the full-length protein,<sup>8,23,24</sup>  
67 including those evoked by AnxA1 on IBDs.<sup>25-28</sup>

68 Based on the data, the pharmacological administration of recombinant AnxA1 or its synthetic N-  
69 terminal-related peptides could address a mandatory role in IBD therapy. Indeed, this approach has been  
70 recently tested using lipid nanoparticles to load recombinant AnxA1 (rAnxA1) or Ac2-26. These strategies  
71 were more effective in treating colitis in mice than free rAnxA1 or Ac2-26 if locally administered, which  
72 demands non-feasible invasive routes of administration to treat chronic patients.<sup>26-28</sup> A nanoparticle-based  
73 on reactive oxygen species (ROS)-responsive material carrying Ac2-26 was effective in colitis treatment by  
74 oral route in mice, based on the release of the peptide by the action of ROS at the inflammatory site.<sup>29</sup> To  
75 strengthen the desirable oral delivery of novel drugs to treat IBDs, here we developed, characterized, and  
76 showed the effectiveness of a simple and cost-effective nanostructured silica mesoporous microparticle  
77 loading Ac2-26 to treat IBD by oral route. Data obtained point out the effectiveness of the treatment as a  
78 promising non-invasive approach to IBD therapy.

79

## 80 **Material and Methods**

### 81 **Materials**

82 SBA-15 was synthesized at the Physics Institute, University of São Paulo, Brazil, according to a  
83 previous work.<sup>30</sup> SBA-15 silanized with the amino-functional trimethoxysilanes (APTES); Eudragit® (L30-  
84 D55; Evonik Industries AG - Rellinghauser Straße – Essen Germany); peptide Ac2.26 (Proteinmax- São  
85 Paulo, Brazil); ethanol were of analytical grade (Sigma; St. Louis, USA); dextran sulfate sodium (DSS, MW  
86 40,000, Dextran Products Limited, Ontario, Canada); anti-mouse MUC-2 (Invitrogen®, Waltham,  
87 Massachusetts, USA); anti-mouse F4/80 (eBioscience™, San Diego, California, USA); anti-mouse Claudin-  
88 1 and secondary antibody anti-rabbit conjugated with HRP (Abcam Plc, Cambridge, United Kingdom); anti-  
89 mouse Ly6G (BD, Becton Dickinson, New Jersey, US); DAB Substrate Chromogen System (Dako Omnis,  
90 Agilent, Santa Clara, California, USA); anti- proliferating cell nuclear antigen (PCNA)(Santa Cruz  
91 Biotechnology, Dallas, Texas, USA); anti-CD163 (Bioss Antibodies Inc, Massachusetts, USA); Collagenase  
92 II and Collagenase IV from *Clostridium histolyticum* and bovine serum albumin (BSA) (Gibco™, New York,

93 USA). ELISA kits anti-mouse TNF, IL-10, CXCL-1, IL-17 and IL-23 (BD OptEIA™ - BD, Becton Dickinson,  
94 New Jersey, US); isoflurane (Cristália Produto Químicos e Farmacêuticos Ltda, São Paulo, Brazil);  
95 paraformaldehyde, xilene, sodium citrate, peroxide and tris (hydroxymethyl) aminomethane (Synth® -  
96 Labsynth Produtos para Laboratórios LTDA, São Paulo, Brazil); cytochalasin D (Millipore Sigma,  
97 Darmstadt, Germany); pluronic P123 (BASF, German); tetraethyl orthosilicate; FITC; amino-functional  
98 trimethoxysilanes (APTES) (Sigma-Aldrich; St. Louis, USA). Cyanine-5.5 NHS ester (Cy5.5 - Lumiprobe  
99 Corporation, Hunt Valley, USA); Spectra/Por® 10 mm dialysis membrane tube (500 Da) (Spectrum®  
100 Laboratories; New Brunswick, USA); J774A.1 cells (ATCC®, Washington DC, USA); Raw 264.7 and Caco-  
101 2 cells (BCRJ®, Xerém, Brazil).

102

### 103 **Synthesis of SBA-15**

104 The synthesis of SBA-15 was made using 4 g of the Pluronic P123 (PEO<sub>20</sub>PPO<sub>70</sub>PEO<sub>20</sub>). It was  
105 dissolved in 122 g of 2M HCl solution and kept under magnetic and mechanical stirring for 1 hour 8.6 g of  
106 tetraethyl orthosilicate was added, and the solution was kept under stirring for 24 hours. After this process,  
107 the mixture was submitted to a 48 hours hydrothermal treatment at 100°C in an autoclave, washed with de-  
108 ionized water, and dried at room temperature. The polymer template was then removed through calcination  
109 at 540°C under N<sub>2</sub> for 2 hours and in air for 4 hours.

110 Ac2-26 incorporation stemmed by dissolving the peptide in MilliQ water, then a 1:1 mixture of SBA-  
111 15:Ac2-26 was made, where 1 mg/mL of Ac2.26 was added at 1 mg of SBA-15. The mixture was dried in  
112 an oven at 35°C until complete drying. For coating with Eudragit® S100, a 1:2 ratio of SBA-15-Ac2-26 and  
113 Eudragit® was added. The material was dried in an oven at 35°C for 4 hours and then stored in a freezer  
114 at -20°C.

115

### 116 **Characterization of SBA-15**

117

118 Dynamic Light Scattering (DLS) measurement was performed at room temperature on a Brookhaven  
119 DM-5000 Particle Size Analyze (Brookhaven Instruments, NY, USA), using a wavelength of 635 nm. Data

120 analysis was conducted using the BIC software provided with the machine. The sample was diluted to 1  
121 mg/mL to mitigate the influence of interparticle interaction on the diffusion coefficient of the particles and,  
122 consequently, on the obtained data.

123 Small-angle X-ray Scattering (SAXS) was performed on a Nanostar (Bruker, Buffalo, USA)  
124 instrument equipped with a microfocus Genix 3D system (Xenocs, Massachusetts, USA) and a Pilatus 300k  
125 detector (Dectris, Baden Switzerland). The sample-to-detector distance was ~667 mm, which provided an  
126 effective range of the modulus of the transfer moment vector,  $q = 4\pi\sin(\theta)/\lambda$  (where  $2\theta$  is the scattering  
127 angle and  $\lambda = 1.5418 \text{ \AA}$  is the X-ray wavelength), from 0.015 to 0.30  $\text{\AA}^{-1}$ . For the experiments, deionized  
128 water (used in the sample preparation) and the same sample from DLS assays were measured, at room  
129 temperature, in reusable quartz capillary with 1.5 mm in diameter mounted on stainless steel cases. Powder  
130 samples of SBA-15 and SBA-15 plus peptide was placed in a sample holder between two mica sheets. The  
131 set of mica sheets was also measured for background correction purposes. Data treatment, which includes  
132 azimuthal integration, background subtraction and absolute scale normalization (for the liquid sample), was  
133 performed using the XSACT software supplied by Xenocs.

134 The adsorption isotherms were obtained in the ASAP2020 equipment (Micromeritics®, Atlanta,  
135 USA) using nitrogen gas.

136

### 137 ***SBA-15 uptake and cytotoxicity***

138 The analysis of SBA-15 uptake into cells was carried out by FITC labelling. For this, it was employed  
139 SBA-15 silanized with APTES, according to protocol described by Appiah-Ntiamoah et al. (2015).<sup>31</sup> After  
140 labeling, SBA-15 was analyzed by SAXS measurements. Mouse macrophage cell line J774A.1 were  
141 cultured and seeded in 24 well plates as previously described.<sup>32,33</sup> Cytochalasin D (20  $\mu\text{M}$ ) was added 1  
142 hour and removed before the treatment with FITC-SBA-15 (10  $\mu\text{g/mL}$ ). The cellular uptake was checked 4  
143 and 24 hours after treatment using the cell imaging (CELENA® Logos Biosystem, USA) and ten fields *per*  
144 condition were analyzed. The percentage of phagocytic cells was quantified using the software ImageJ. In  
145 addition, cytotoxicity for different concentrations of SBA-15 was performed using MTT assay.<sup>34</sup>

146 Murine 3D organoids and organoid-derived differentiated epithelial cells were isolated and cultured  
147 as previously described.<sup>35,36</sup> FITC-SBA (10 µg/mL) was added into organoids and on the apical part of the  
148 differentiated epithelial cells and analyzed 6 days or 24 hours later, respectively.

149

#### 150 ***In vitro release of peptide by SBA-15***

151

152 The peptide Ac2-26 was dissolved in phosphate buffered saline (PBS) (pH of 7.4) to reach a  
153 concentration of 1.0 mg/mL. Simultaneously, 1 mg of Cy5 dye was dissolved in 1 mL of 1 mM DMSO. The  
154 peptide and Cy5 dye were mixed in a 1:10 molar ratio, and any excess dye was removed through dialysis  
155 using a 10 mm membrane with a 500 Da cutoff. The Cy5-labeled peptide was purified with Sephadex G-25  
156 and then lyophilized. Spectrophotometry at 215 nm (Shimadzu Scientific, Marlborough, USA) confirmed the  
157 success of the labeling process. The yield of the Cy5-labeled peptide was ten vials, each containing 450  
158 µg.

159 Following, the labelled peptide was incorporated to SBA-15 (following item 2.2) and employed to test  
160 the release of the peptide into cells. The uptake of SBA-15-Ac2-26Cy5.5 and FITC-SBA-15 was measure  
161 by flow cytometry (BD, Accuri C6, USA) in mouse macrophages Raw 264.7 and Caco-2 human intestinal  
162 epithelial cells. The presence of the peptide Ac2-26Cy5.5 was analyzed after 30 minutes, 2, 6 and 24 hours  
163 after incubation with SBA-15-Ac2-26Cy5.5. Caco-2 cell were used to measure the uptake of FITC-SBA-15  
164 after 4 and 24 hours of incubation. After the incubation time, cells were collected and washed twice and  
165 resuspended in PBS. In order to quantify the percentage of cell positive, at least 10,000 events were  
166 collected. The events were collected with the delimitation of the principal population of healthy cells, and  
167 the percentage was set in relation to the untreated condition.

168

#### 169 ***Animals***

170 Male C57BL6 wild-type (WT) mice were obtained from Faculty of Pharmaceutical Sciences of the  
171 University of São Paulo, aged 8–10 weeks and weighting 20–25 g. They were maintained under pathogen-  
172 free conditions and in a 12-hours light/dark cycle, at temperatures between 20 to 25°C, with free access to

173 water and food. The protocol of study was approved by the Ethics Committee of Animal Use of the Faculty  
174 of Pharmaceutical Sciences of the University of São Paulo (CEUA/FCF/ USP; protocol n°653), following  
175 the Brazilian laws of animal ethics.

176

#### 177 ***In vivo and ex vivo evaluation of SBA-15 and Ac2-26 in gastrointestinal tract***

178 The homing of the SBA-15 in the gastrointestinal tract (TGI) was evaluated by FITC-SBA-15 coated  
179 with Eudragit. Eudragit-FITC-SBA-15 (400 µg/400 µL) was administered orally to health mice at day 6.  
180 Animals were euthanatized 6 or 18 hours later to withdraw of the TGI. *Ex vivo* fluorescence images were  
181 acquired using the IVIS ® Lumina LT Series III equipment (Xenogen Corp., Alameda, CA, USA) using the  
182 following parameters: excitation/emission 465/520, automatic exposure time, F/stop 4 and binning of 4. For  
183 Fluorescence intensity analysis we selected a region of interest and normalized by the corresponding areas.  
184 The signals acquired were analyzed using Living Image Software version 4.7.2 in units of photons/s.

185

#### 186 ***Experimental Colitis***

187 Experimental colitis was induced by gavage (v.o.) of dextran sodium sulfate (DSS) at 2%, conveyed  
188 in the water of the animals from day 0-6, so that they receive constant doses of DSS. The animals were  
189 divided into four groups: DSS, DSS + SBA-15-Eudragit (200 µg) and DSS + SBA-15-Ac2.26-Eudragit-SBA-  
190 15-Ac2.26 (200 µg/200 µg), both in a final volume of 400 µL. Treatments were performed daily by oral route,  
191 between days 6 @ Naive or DSS groups were manipulated as the other groups, but with the carrier solution  
192 PBS only (Supplementary Figure 1). Clinical parameters (body weight, diarrhea, and rectal bleeding) were  
193 evaluated daily (Day 0 to day 10), to assess the evolution of the colitis. The Disease Activity Index (DAI)  
194 was calculated from the sum of the clinical parameters. On day 10, the animals were anesthetized by  
195 isoflurane inhalation (2-chloro-2-(difluoromethoxy)-1,1,1-trifluoroethane) and euthanized. The intestinal  
196 length and macroscopic analyses were evaluated. Colon samples were collected from the ileocecal junction  
197 up to the proximity of the anus, and employed to histological (distal colon), enzymatic and flow cytometry  
198 (mid/proximal colon) analyzes.

199

## 200 **Histopathological analysis**

201 Fragments collected from the distal part of the colon were fixed by 24 hours incubation in 4%  
202 paraformaldehyde for 24 hours. Histopathological analysis was performed in 4  $\mu$ m sections. Samples were  
203 stained using hematoxylin and eosin solution and analyzed using an AxioCam coupled to a Zeiss  
204 microscope (Carl Zeiss, Jena, Germany). The histopathological score analysis was performed blindly by  
205 two analysts knowledgeable on characteristics of intestinal tissue. The score was adapted and considered:  
206 tissue edema, dysplasia/altered histoarchitecture, crypt edema, inflammatory infiltrates, and ulcerations.  
207 Ten photos were taken of each histological section using a 20x high power objective and scores were  
208 evaluated on a scale ranging from 0 to 4.

209

## 210 **Immunohistochemistry analysis**

211 Colon sections were deparaffinized, hydrated and incubated with sodium citrate buffer (pH 6.0) at  
212 96°C for 30 minutes. Endogenous peroxidase activity was blocked with 3% hydrogen peroxide, three times  
213 washed after each in 10 minutes of incubation. Next, blocking of unspecific binding sites was carried out  
214 with 1% BSA diluted in Tris-buffer saline (TBS) for one hour. Sections obtained were incubated with  
215 antibodies for: Claudin-1 (1:50), MUC-2 (1:200), PCNA (1:10) and CD163 (1:100). Afterwards they were  
216 washed and incubated with a secondary antibody conjugated with HRP (1 hour, room temperature), and  
217 detected using 3,3'-diaminobenzidine. The sections were photographed using an AxioCam coupled to a  
218 Zeiss microscope (Carl Zeiss, Jena, Germany) with a 40x high power objective. The percentage of marked  
219 area of Claudin-1 was quantified using ImageJ software. Results were expressed as mean  $\pm$  S.E.M. of  
220 percentage of marked area. The quantification of MUC-2, PCNA and CD163 were evaluated by using a 40x  
221 high power objective in ten fields of the mucosal layer from sections and the number of positive cells were  
222 quantified for each field assessed. Results were expressed as mean  $\pm$  S.E.M. of cells per field.

223

## 224 **Isolation of Leukocytes from Lamina Propria and Flow Cytometry**

225 Leukocytes from proximal colonic lamina propria were isolated after washes with 2 mM EDTA  
226 followed by digestion with collagenase II and IV from *Clostridium histolyticum* (1 mg/mL). The cells were

227 washed through 40- $\mu\text{m}$  strainers (Corning, Corning, NY, USA) and stained with Ly6G (PE) and F4/80  
228 (PerCpCy5.5). Positive populations were determined by labeling with single antibodies. A minimum of  
229 10,000 events per sample were acquired on a BD Accuri C6 Flow Cytometer (BD, Becton Dickinson, New  
230 Jersey, US). The results were expressed as percentages of positive cells normalized by controls from each  
231 experiment.

232

### 233 **Statistical Analysis**

234 The experimental colitis was subjected to analysis of clinical parameters using Two-way ANOVA with  
235 a subsequent Bonferroni post-test. In addition, for other analyses, One-way ANOVA was utilized, follow'd  
236 by Tukey's post-test. The significance level was set at  $p < 0.05$ , and the results were presented as mean  $\pm$   
237 SEM. GraphPad Prism Software 7.0 was employed to conduct the statistical analyses.

238

## 239 **Results**

### 240 ***Ac2-26 solution is composed of rod-like particles***

241 Ac2-26 was successfully dispersed in deionized water at a concentration of 6 mg/mL, allowing  
242 future experiments that could require higher concentrations. It is interesting to observe that the sample is  
243 more viscous than pure water and slightly hazy, which points out the likely existence of large aggregates,  
244 being those features mitigated after dilution. To probe such aggregates, we proceeded with DLS assays.  
245 Figure 1A shows the obtained autocorrelation function (black filled circles),  $C(\tau)$ , fitted with the non-  
246 negatively constrained Least Squares (NNLS) method<sup>37</sup> (red continuous line). From the satisfactory fitting,  
247 the size distribution weighted by intensity, volume and number was evaluated (inset of Figure 1A). As  
248 observed, there are three populations of particles with sizes  $(23 \pm 1)$  nm,  $(109 \pm 28)$  nm and  $(58 \pm 18)$   $\mu\text{m}$ ,  
249 being the first one the most numerous. Considering the results, none of these sets correspond to the peptide  
250 alone, with only 3089.46 Da of molecular weight, as informed by the manufacturer, but its self-assembled  
251 supramolecular structure and even aggregates. It is important to realize that such type of analysis assumes  
252 a spherical shape for the probed objects. To confirm this feature, we performed SAXS experiments on the  
253 same sample used for DLS.

254 The obtained SAXS data is shown in Figure 1B (black filled circles), and it was satisfactorily fitted  
255 by the Indirect Fourier Transform (IFT),<sup>38</sup> implemented in the WIFT software [38]. From the fitting (blue  
256 continuous line), the so-called pair distance distribution,  $p(r)$ , is obtained (inset of Figure 1B, blue continuous  
257 line), which provides the particle's longest length of  $\sim 23$  nm (where  $p(r) \approx 0$ ), in agreement with the DLS  
258 results concerning the population with the smallest objects. Furthermore, the pair distance distribution,  $p(r)$ ,  
259 suggests the presence of elongated particles, for instance, with rod shape. In this context, a test was  
260 performed in which the SAXS data was fitted with a simple cylinder model. A lognormal size distribution for  
261 the radii values was also used, as in previous works.<sup>39</sup> The obtained satisfactory fit (Figure 1B, red  
262 continuous line), corroborates the hypothesis of the cylindrical shape. In this case, the objects have average  
263 radius of  $\sim 3$  nm, according to the obtained size distribution (inset of Figure 1B, red continuous line) and  
264 length of  $\sim 80$  nm. The former value is out of the probed scale length, defined by the minimum value of the  
265  $q$  range, thus it cannot be precisely determined. Thus, the value indicated by the  $p(r)$  function,  $\sim 23$  nm, was  
266 assumed as the cylinder length.

267 All in all, SAXS and DLS results suggest the peptide self-assembly into rod-shaped particles.

268

### 269 ***SBA-15 is a suitable mesoporous to anchorage Ac2-26***

270 The incorporation of peptide into SBA-15 was around  $88,8\% \pm 1.2$  ( $n=4$ )  $88,8\%$ , measured by the  
271 Bradford dye-binding method. SAXS measurements were performed on powder samples of pure SBA-15  
272 and SBA-15 containing the peptide (sample SBA-Ac-26). The obtained data is shown in Figure 1C (black-  
273 filled circles) and the obtained results are comparable to already reported for ordered mesoporous silica  
274 data.<sup>40-42</sup> It is interesting to note that both curves, with and without peptide, are very much alike.

275 To quantitatively describe their nanostructure and eventual differences, we proceeded with the data  
276 analysis using the model fully detailed by Losito *et al* 2021a.<sup>41</sup> The main fitting parameters, as well as their  
277 values, are summarized in Table 1, while their meaning is explained in the following:  $R$  and  $T$  correspond  
278 to the core radius and the shell thickness, respectively, of the core-shell cylinder modeling the mesopores,  
279 being  $\sigma_{rel}$  the shared standard deviation of the log-normal size distribution of  $R$  and  $T$ . The parameter  
280  $\frac{\Delta\rho_{core}}{\Delta\rho_{shell}}$  informs about the contrast electron density of the core relative to the shell. For ideally "empty"

281 mesopores,  $\frac{\Delta\rho_{core}}{\Delta\rho_{shell}} = 0$ . Otherwise,  $\frac{\Delta\rho_{core}}{\Delta\rho_{shell}} \neq 0$  is an indication about the existence of some material inside  
282 the mesopores.  $a$  is the lattice parameter and  $\sigma_a$  quantifies the distortion of the lattice relative to an ideal  
283 2D-hexagonal one (for an ideal lattice,  $\sigma_a = 0$ ). Finally,  $AP$  is the scale factor of the Porod term (proportional  
284 to  $q^{-4}$  decaying law) and monitors, for instance, changes at the low  $q$  region of the SAXS curve related to  
285 the presence of large aggregates, while  $R_{G_{polymer}}$  is the radius of gyration related to the polymer-like  
286 scattering at high  $q$  originated from the synthesis of the SBA-15.

287 As expected, both curves have structural parameters with close values, except for the  $AP$   
288 parameter. In comparison to pure SBA-15, its value increased  $\sim 3$  times with the addition of peptide, which  
289 suggests the presence of material on the SBA-15 macroporosity. Moreover, the parameter  $\Delta\rho_{core}/\Delta\rho_{shell}$   
290 slightly increased with the peptide incorporation, indicating that a fraction of material is inside the  
291 mesopores. Considering the percentage of peptide anchorage was 87%, as previously discussed, possibly  
292 most of the Ac-26, in its aggregated/self-assembled form, is in the SBA-15 macroporosity.

293 To have more information on the SBA-15 pore filling by the peptide, NAI experiments were  
294 performed. The sorption results related to the SBA-15 samples, pristine and loaded with Ac2-26  
295 (peptide:silica, 1:35 wt%), are shown in Figure 1D and are similar to those reported by Zhao et al 1998,<sup>43</sup>  
296 for SBA-15 material. The isotherm of both samples shows hysteresis loops with sharp adsorption and  
297 desorption branches, which indicates a narrow pore size distribution (PSD). From the quantitative analysis  
298 using the Brunauer–Emmett–Teller (BET) and Barrett–Joyner–Halenda (BJH) models as well as the  
299 calculations based on previous works,<sup>44</sup> the PSD was obtained (inset of Figure 1D) along other useful  
300 parameters summarized in Table 1. Although the PSD of both samples are very similar, data presented in  
301 Table 1 show a reduction of around  $\sim 55\%$  in the surface area (internal mesoporosity/external  
302 macroporosity) after the incorporation of the peptide into SBA-15. Also considering the reduction of  $\sim 62\%$   
303 in the available mesopore volume, that can either indicate their filling or blocking of the pore entrance, we  
304 can conclude that the peptide is located inside the silica porosity (mesopores and/or macropores). In  
305 combination with SAXS results, the hypothesis that likely most of the peptide is in the SBA-15 macroporosity  
306 is reinforced. Furthermore, the possibility of increase the peptide concentration is evident, since there is  
307 still “free space” in the SBA-15 porosity, with the care of preserving a homogenous distribution.

308

309 ***SBA-15 does not cause cytotoxicity and releases Ac2-26***

310 Fluorophore labeling was employed to investigate the uptake of SBA-15 and the release of the Ac2-  
311 26 by SBA-15 into cells. SAXS measurement showed the incorporation of fluorophore to SBA-15 without  
312 robust changes in the SBA-15 scattering profile (Supplementary Figure 2). We here show the low uptake  
313 of SBA-15 by differentiated colonic epithelial cells (Figure 2A and D, Supplementary Figure 3) and 3D  
314 colonic organoids (Figure 2B, Supplementary Figure 3), which indicate SBA-15 may be low absorbed in the  
315 gut. Moreover, further flow cytometry analysis confirmed this data (Supplementary Figure 4). Nonetheless,  
316 enhanced epithelial permeability or even disruption of the epithelial barrier that occurs during gut  
317 inflammation may favor the microparticle influx into tissue.

318 Hence, SBA-15 may be taken up by phagocytes in the inflamed tissue. Data presented in Figure 2C  
319 showed that J774 murine macrophages engulfed the microparticle by phagocytosis, as the percentage of  
320 intake was blocked by cytochalasin D with a concentration of 20  $\mu$ M. The uptake of microparticles increased  
321 with time (Figure 2E and F) and did not cause cytotoxicity until 48 hours of incubation (Figure 2G). Indeed,  
322 these data corroborate previous data depicting SBA-15 as a promising drug carrier into epithelial cells in  
323 the gut and inflammatory phagocytes.<sup>45</sup>

324 To evaluate the delivery of Ac2-26 by SBA-15, Caco-2 epithelial cells were incubated with SBA-15  
325 loading Ac2-26-Cy5.5 labeled. Flow cytometry assay detected fluorescence emitted by Ac2-26-Cy5.5 in the  
326 epithelial cells after 30 minutes of incubation, which was increased 6 hours after incubation (Figure 2H).  
327 Furthermore, similar data was found in Raw 264.7 macrophages, which also evidences the capability of  
328 SBA-15 to deliver the peptide into phagocytes (Figure 2H).

329

330 ***Eudragit-SBA-15 biodistribution in gastrointestinal tract (GIT) and peptide release***  
331 ***into gut***

332 Notably, the in vitro dissolution analysis showed that the Ac2-26 peptide was released from Eudragit-  
333 SBA-15 in a pH solution close to that found in the duodenum (Supplementary Figure 5). Hence, to confirm  
334 if the peptide was delivered into the gut, Eudragit-SBA-15-Ac2-26Cy5.5 was orally administered, and the

335 intensity of fluorescence was achieved in GIT after 3 hours of administration, which remained until 8 hours  
336 of analysis (Figure 3A and B).

337 To evaluate the transit of Eudragit-FITC-SBA-15 in the GIT conditions and achieve the large intestine,  
338 we track the treatment 6 and 18 hours after oral administration into mice. The measurement of signals  
339 detected the Eudragit-FITC-SBA-15 in the small and large intestines at 6 hours and 18 hours after  
340 administration, respectively (Figure 3C and D).

341 Associated data obtained showed Eudragit-SBA-15 remains in the GIT for at least 18 hours, which may  
342 lead to sustained release of the peptide into the gut, addressing further analysis of the therapeutic efficacy  
343 of the Eudragit-SBA-15-Ac2-26 by oral route on IBDs.

344

#### 345 ***Eudragit-SBA-Ac2-26 reduces clinical symptoms and inflammation in the gut***

346 DSS-induced colitis is a standard model of experimental IBD.<sup>46</sup> DSS administration orally triggers the  
347 peak of the disease on day 6, and the withdrawal of DSS promotes the initial recovery of tissue on day  
348 10.<sup>16,22,29,47</sup> Hence, the Oral Eudragit-SBA-15-Ac2-26 treatment started at the peak of the disease (day 6)  
349 and was maintained at the beginning of the recovery phase (day 10). Treatments were performed once a  
350 day based on the TGI distribution of SBA-15 and peptide release. Data obtained showed that Eudragit-  
351 SBA-15-Ac2-26 oral administration prevented weight loss and induced colon length recovery, leading to  
352 lower DAI (Figure 4A-C). Moreover, the treatment inhibited the influx of neutrophils and macrophages into  
353 the inflamed gut, reduced the secretion of inflammatory cytokines TNF- $\alpha$  and CXCL-1, and enhanced the  
354 secretion of the anti-inflammatory cytokine IL-10 (Figure 4D-H). The beneficial effects of the treatment were  
355 due to Ac2-26 loading, as treatment with Eudragit-SBA-15 did not prevent clinical symptoms and  
356 inflammation parameters (Figure 4A-H).

357

#### 358 ***Eudragit-SBA-Ac2-26 improves the gut histoarchitecture***

359 Histological analysis of the tissue showed that DSS administration induced ulcers, crypt abscesses,  
360 vacuolar hydropic degeneration, submucosal edema, and mucosal/submucosal massive inflammatory cells

361 infiltrate. These alterations were reduced, and the colonic histological architecture was recovered by the  
362 Eudragit-SBA-15-Ac2-26 oral treatment (Figure 5A).

363 Immunohistochemical analysis was carried out to depict the mechanisms involved in the protection  
364 of gut architecture caused by Eudargit-SBA-15-Ac2-26 treatment. DSS administration led to lower  
365 expression of claudin-1, one major component of tight junctions, essential for the epithelial cells' barrier  
366 integrity; reduced mucin-2 marker, associated with goblet cells, leading to impaired mucus secretion;  
367 reduced epithelial cell proliferation and reduced the amount of anti-inflammatory M2 macrophage in the  
368 tissue. Eudragit-SBA-15-Ac2-26 oral treatment rescued all effects on tissue architecture (Figure 5B-E).

369

## 370 Discussion

371 The oral route is the most preferred for drug administration to treat IBD as it is not invasive, allows  
372 high patient compliance and flexibility on dose adjustment, and delivers the drug directly to the colonic  
373 region.<sup>46</sup> Nonetheless, small molecules and proteins present poor bioavailability by oral route administration  
374 and require suitable pharmaceutical technical approaches to resist the bacterial and enzyme-rich  
375 environment and different pHs in the gastrointestinal system.<sup>46</sup> Based on the robust beneficial actions of  
376 AnxA1 on IBD, we here inferred that AnxA1 mimetic peptide Ac2-26 could be incorporated into the SBA-15  
377 ordered mesoporous silica microparticle, and the polymer coverage, using the well-known Eudragit® (L30  
378 D55 polymer, Evonik), could protect the SBA-15-Ac2-26 from the unwanted harms of the TGI to deliver  
379 Ac2-26 into the inflamed colon area.

380 SBA-15 has a high thermic, hydrothermal, and mechanic-resistant material,<sup>43</sup> conferring its ability  
381 to resist pH and enzymatic actions [46]. The structural components of SBA-15 contain many essential  
382 sylanol groups (Si-OH)<sup>43,48</sup> to bond substances in its structure. SBA-15 also presents a high surface area,  
383 large pore volume, and narrow mesoporous pore size distribution, around 10 nm. Together, these properties  
384 allow the safe transport of small molecules through the TGI.<sup>49-54</sup> In fact, by means of the modeling of SAXS  
385 data, in combination with NAI results, it was possible to conclude that a fraction of the Ac2-26 peptide is  
386 loaded into the SBA-15 mesopores. In contrast, the remaining amount is somehow on the silica surface, a  
387 similar scenario observed in previous studies,<sup>42,55</sup> in which the authors loaded proteins instead of peptides.

388 As suggested by Rasmussen et al (2019),<sup>56</sup> the biological content of the SBA-15 macroporosity is still being  
389 protected against harsh environmental conditions such as the TGI.

390 Positively charged molecules can undergo electrostatic interactions with anionic components such  
391 as glycoproteins expressed on the epithelial cells. This results in charge neutralization and alteration of the  
392 tight junctions' permeability, allowing the transport of positively charged molecules.<sup>57</sup> For this reason, SBA-  
393 Ac2-26 was further covered with Eudragit®, a pH-responsive anionic copolymer produced from methyl  
394 methacrylate and methacrylic acid. It exhibits pH-dependent solubility characteristics, remaining stable  
395 under acidic conditions but dissolving in basic pH (pH >7.0)<sup>58</sup> to facilitate drug release, which in  
396 physiological conditions can start in the distal ileum. Eudragit is an efficient drug carrier in the lower pH of  
397 the inflamed gut, as it carries a significant negative charge,<sup>59</sup> enabling its preferential absorption to sites of  
398 inflammation. Image tomography analysis corroborated that Eudragit-SBA-15 administered by oral route  
399 remained in the GIT for an extended period, suitable for delivering drugs to the gut. Moreover, the Eudragit-  
400 SBA-15 uptake by *in vitro* gut epithelial cells in two or tri-dimensional cell models was deficient, reinforcing  
401 the hypothesis that SBA-15 is not absorbed in the gut and could be excreting by feces.<sup>45</sup> Further data  
402 addressed Eudragit-SBA-15 as a suitable platform to deliver the peptide into the gut, as Ac2-26 was  
403 detected in the epithelium after *in vitro* incubation with SBA-15-Ac2-26, and Eudragit-SBA-15 delivered  
404 Ac2-26 into the gut for an extended period after oral administration.

405 The inflammatory environment disrupts the intestinal barrier in IBD, resulting in increased  
406 permeability, allowing the leakage of nanoparticle-based therapies to the lamina propria and the subsequent  
407 engulfment by phagocytes.<sup>60-62</sup> It may be a suitable mechanism of SBA-15-Ac2-26 in IBD, as we here  
408 corroborated that macrophage efficiently phagocyte SBA-15.

409 The beneficial effects Ac2-26 on IBD symptomatology are related to its binding to FPR1 on the  
410 inflamed epithelium.<sup>25,26</sup> Moreover, AnxA1 is highly expressed by neutrophils and macrophages in the  
411 lamina propria and mediates the efferocytosis via FPR2 agonism.<sup>16,22</sup> Ac2-26 acts like AnxA1, binding to  
412 both receptors for downstream anti-inflammatory and tissue repair through intracellular pathways.<sup>63</sup> These  
413 concepts can be addressed to SBA-15 distribution and Ac2-26 biological response to oral treatment of  
414 colitis. The treatment promoted rapid beneficial effects, detected by the marked reduction of weight loss 24  
415 hours after the first treatment, which was sustained for the following three administrations once a day during

416 the recovery phase of the disease. The effectiveness of the oral treatment of colitis could not be compared  
417 to the free Ac2-26 administration due to the poor bioavailability of peptides by oral intake.<sup>64</sup> On the 10<sup>th</sup> day  
418 of the disease, the treatment inhibited the influx of neutrophils and monocytes into inflamed tissue and  
419 reduced the levels of pro-inflammatory cytokines secreted in the tissue. The latter effect could reflect the  
420 lower number of inflammatory cells. Indeed, Ac2-26, similarly to AnxA1, detaches adhered cells to  
421 endothelial cells, thus limiting their trafficking to inflamed sites;<sup>65-67</sup> nonetheless, Ac2-26 inhibits the  
422 secretion of pro-inflammatory cytokines by transcriptional and post-transcriptional pathways.<sup>28,68</sup>  
423 Conversely, levels of the anti-inflammatory and pro-resolution IL-10 cytokine were enhanced by the  
424 treatment and agreed with the high amounts of anti-inflammatory CD163 M2 macrophages in the tissue of  
425 treated mice. Ac2-26 is a recognized resolvin peptide that polarizes M2 macrophages and induces  
426 neutrophil apoptosis to further phagocytosed by M2 macrophages.<sup>27,28,65-67</sup>

427 Beyond reducing inflammation, Eudragit-SBA-15-Ac2-26 treatment favored tissue repair by rescuing  
428 the tight adhesion molecule and claudin-1 expression and promoting epithelial cell proliferation. Such  
429 AnxA1 as Ac2-26 induces epithelial repair in different models, and the underlying mechanisms involve the  
430 binding to FPR1/FPR2 receptors to downstream ERK1/2 phosphorylation pathway and inhibition of RhoA-  
431 ROCK signaling.<sup>27,69-75</sup>

432

## 433 **Conclusion**

434 We here designed a polymer-covered microparticle containing the antiinflammatory peptide Ac2-26  
435 as a platform for targeted drug delivery to the inflamed colon by oral route administration. This conception  
436 was based on the high incorporation of small molecules into the microparticle mesoporous, which polymers  
437 could cover to protect it from the TGI adversities to drug delivery. Indeed, around 88% of the Ac2-26 peptide  
438 was incorporated, and the massive peptide release occurred in pH close to the gut microenvironment,  
439 suggesting that the peptide could be effectively protected from premature release until it reached the ileum  
440 and colon. Further data corroborated the platform's efficiency, as Eudragit-SBA-15 reached the large  
441 intestine in 18 hours, delivered the peptide in the gut, and clinical colitis recovery was detected in the first  
442 24 hours of treatment. After four doses, once a day, the inflamed tissue was recovered, showing the  
443 peptide's anti-inflammation and tissue repair actions. Therefore, this platform holds promise, particularly in

444 safeguarding and delivering Ac2-26 at the inflamed colon to trigger the distinct intracellular pathways, which  
445 are recognized as underlying mechanisms of AnxA1 protection in IBDs.

654 **Legend for Figures**

655 **Figure 1 A** Autocorrelation function (filled black circles) fitted by the NNLS method (continuous line). Inset:  
656 Hydrodynamic diameter distributions of the peptide weighted by number, volume, and intensity. **B** SAXS  
657 data of the peptide in solution (filled circles) fitted by the IFT method (blue continuous line) and the cylinder  
658 model (red continuous line). Inset: The obtained  $p(r)$  function, from IFT, and the size distribution function of  
659 the cylinder radius,  $N(D)$ , from the model fitting. **C** SAXS data (filled black circles) of the pure SBA-15 and  
660 the SBA-15 incorporated with Ac2-26 (sample SBA-Ac2-26) fitted by the SBA-15 model (red continuous  
661 line). The curves were vertically shifted for a clearer visualization. **D** NAI data of pristine SBA-15 and the  
662 SBA-15 incorporated with Ac2-26 (sample SBA-Ac-26). Inset: Pore size distribution (PSD, adsorption and  
663 desorption).

664

665 **Figure 2 A** Representatives pictures from differentiated EDMs treated FITC-SBA for 24 hours. **D** The  
666 percentage of microparticles uptake was determined. **B** Representative pictures showed 3D murine  
667 organoid challenged with microparticles and cultured for 6 days. **C** Representative pictures showed  
668 macrophages *J774* challenged or not with microparticles for 24 hours in presence or absent of phagocytosis  
669 inhibitors (cytochalasin D). **E** and **F** represent the uptake quantification of FITC-SBA after 4 hours (4h) and  
670 24 hours (24h) after treatment. **G** In All images, green inside the cells represent microparticles  
671 internalization. Cytotoxicity by MTT assay using murine macrophages Raw 264.7. Ac2-26, SBA and  
672 Ac2-26-SBA concentrations 1, 2, 3 and 4 corresponding to 0.5, 5, 10 and 50  $\mu\text{g/mL}$  respectively. **H**  
673 Representative graph showing the percentage of Caco-2 or Raw 264.7 cells positive for Ac2-26-Cy5 at  
674 different time points: 30 minutes (30min), 2 hours, 6 hours and 24 hours. The lower left side represents the  
675 Caco-2 and Raw 264.7 histogram median of fluorescence (upper line) and the percentage using forward  
676 scatter height (FSC-H) vs fluorescence emission for Cy5. Data obtained from the flow cytometry Accuri C6  
677 software after 30 min and 24 hours. **D** as determined by parametric Student's t-test. **E** and **F** as determined  
678 by One-Way ANOVA and Tukey multiple comparisons. **H** as determined Two-Way ANOVA and Tukey  
679 multiple comparisons. \*  $p < 0.05$ , \*\*  $p < 0.01$  and \*\*\*\*  $p < 0.0001$ . #####  $p < 0.0001$ .

680

681 **Figure 3** Biodistribution along the TGI of Eudragit-SBA-Ac2-26Cy5.5 Eudragit-FITC-SBA-15. Mice were  
 682 treated orally and the intensity of the distribution is represented by photons/s. A Eudragit-SBA-Ac2-26Cy5.5  
 683 distribution was analyzed after 3 hours and 8 hours *in vivo* (top) and the TGI analyzed separately *ex vivo*  
 684 (botton) at the same time points. The yellow color represents the higher intensity in the tissue. B Eudragit-  
 685 FITC-SBA-15 biodistribution *ex vivo* along the TGI after 6 hours and 18 hours. The red color represents the  
 686 higher intensity in the tissue.

687

688 **Figure 4** Clinical, cellular and secretory profile of DSS-induced colitis mice treated with Eudragit-SBA or  
 689 Eudragit-SBA-Ac2-16. A Percentage of body weight loss; B Anatomic evaluation of the colon and length  
 690 measure; C DAI; D Percentage of macrophages isolated from lamina propria (CD45<sup>+</sup>/F4/80<sup>+</sup>); E Percentage  
 691 of neutrophils isolated from lamina propria (CD45<sup>+</sup>/Ly6G<sup>+</sup>); F TNF- $\alpha$ ; G CXCL-1; H IL-10. n = 10 mice/group.  
 692 \* p < 0.05, \*\* p < 0.01, \*\*\* p < 0.001 vs DSS. & p < 0.05, && p < 0.01, &&& p < 0.001 vs Eudragit-SBA-15.  
 693 Abbreviations: DAI, disease activity index. DSS, dimethyl sulfoxide.

694

695 **Figure 5** Histopathological sections performed with HE dye. A Histopathological score represented by  
 696 arbitrary units. The sections were blindly evaluated and considered alterations were highlighted. Tissue  
 697 edema (square brackets), inflammatory infiltrates (black arrow head) and ulcerations (red arrow). Naïve  
 698 section presenting normal histoarchitecture. Mice colon sections submitted to IHC. B Representative  
 699 sections and percentage (%) of marked area for Claudin-1 marker. C Representative sections and, number  
 700 of positive cells per field for MUC-2 marker. D Representative sections and, number of positive cells per  
 701 slide for PCNA marker. E Representative sections and, number of positive cells per field for CD163 marker.  
 702 n = 10 mice/group. Scale bar: 50  $\mu$ m. Sections: 4  $\mu$ m. \* p < 0.05, \*\* p < 0.01, \*\*\* p < 0.001, \*\*\*\* p < 0.0001  
 703 vs DSS. . & p < 0.05, &&& p < 0.0001 vs DSS + Eudragit-SBA-15.

704

705 **Table 1** Structural and textural properties of the pristine SBA-15 sample and the SBA-15 incorporated with  
 706 Ac2-26 (sample SBA-Ac-26) obtained from SAXS and NAI techniques. All uncertainties in the last digit,  
 707 when exist, are presented between parentheses.

## Anexo 5. Currículo lattes

### Milena Fronza Broering

Endereço para acessar este CV: <http://lattes.cnpq.br/5303105654305538>

ID Lattes: 5303105654305538

Última atualização do currículo em 30/11/2023

Possui graduação em Biomedicina pela Universidade do Vale do Itajaí - UNIVALI (2016), Mestre em Ciências Farmacêuticas pela Universidade do Vale do Itajaí (2019), área de concentração em Produtos Naturais e Substâncias Bioativas. Aluna de doutorado no programa de Pós-Graduação em Fisiopatologia e Toxicologia da Faculdade de Ciências Farmacêuticas da Universidade de São Paulo (FCF/USP) atuando na linha de pesquisa sobre processo inflamatório e nanotecnologia. **(Texto informado pelo autor)**

### Endereço

### Formação acadêmica/titulação

2017 - 2019

Mestrado em Programa de Mestrado em Ciências Farmacêuticas.  
Universidade do Vale do Itajaí, UNIVALI, Brasil.  
Título: Efeitos do extrato de *Tithonia diversifolia* (Asteraceae) sobre a inflamação inata,  
Ano de Obtenção: 2019.

Orientador: José Roberto Santin.

Coorientador: Nara Lins Meira Quintão.

Bolsista do(a): Conselho Nacional de Desenvolvimento Científico e Tecnológico, CNPq, Brasil.

Palavras-chave: Inflamação; Migração; Neutrófilos; *Tithonia*.

Grande área: Ciências Biológicas

Grande Área: Ciências Biológicas / Área: Farmacologia / Subárea: Imunologia Celular.

Graduação em Biomedicina.

2013 - 2016

Universidade do Vale do Itajaí, UNIVALI, Brasil.

Título: Avaliação toxicológica in vivo, in vitro e in silico do extrato metanólico e compostos isolados das partes aéreas de *Rubus rosaefolius*.

Orientador: José Roberto Santin.

2010 - 2012

Bolsista do(a): Programa Universidade para Todos, PROUNI, Brasil.

Ensino Médio (2º grau).

Escola de Educação Básica Luiz Bertoli, EEELB, Brasil.

### Formação Complementar

2019 - 2019

Cultivo Celular em 3D. (Carga horária: 32h).

Banco de Células do Rio de Janeiro, BCRJ, Brasil.

### Atuação Profissional

Universidade de São Paulo, USP, Brasil.

### Vínculo institucional 2019 - Atual

Vínculo: Bolsista, Enquadramento Funcional: Doutorado, Carga horária: 40, Regime: Dedicção exclusiva.

### Idiomas

Português Compreende Bem, Fala Bem, Lê Bem, Escreve Bem.  
Inglês Compreende Bem, Fala Bem, Lê Bem, Escreve Bem.

### Produções

### Participação em eventos, congressos, exposições e feiras

1. V Congresso da Associação Brasileira de Ciências Farmacêuticas. Efeitos da nanocápsula de núcleo lipídico contendo anexina a1 em modelo de colite ulcerativa induzida em camundongos. 2020. (Congresso).
2. I Simpósio Internacional em Investigação Químico Farmacêutica. Avaliação da Atividade Anti-inflamatória do Extrato de Tithonia diversifolia (Asteraceae). 2018. (Simpósio).
3. IV Congress of the Brazilian association of Pharmaceutical sciences - Biological Drugs: From Technologies to Pharmaceutical Care. ETHANOLIC EXTRACT OF Tithonia diversifolia (ASTERACEAE) LEAVES INHIBITS NEUTROPHIL INFLUX AND CYTOKINE SECRETION. 2018. (Congresso).
4. IV Semana Integrada: Ensino, Pesquisa e Extensão do Centro de Ciências da Saúde - CCSias. 2016. (Outra).
5. VI Simpósio Biomédico e VIII Semana de Iniciação Científica de Biomedicina. 2016. (Simpósio).
6. Grupo de Pesquisa em Análises Clínicas. 2015. (Outra).
7. Grupo de Pesquisa em Farmacologia. Avaliação toxicológica in vivo, in vitro e in silico do extrato metanólico e compostos isolados das partes aéreas de Rubus rosaefolius. 2015. (Outra).
8. Grupo de Pesquisa em Farmacologia. 2015. (Outra).
9. III Congresso de Biomedicina de Santa Catarina. Avaliação toxicológica in vivo e in silico do extrato e compostos isolados das partes aéreas de Rubus rosaefolius. 2015. (Congresso).
10. III Congresso de Biomedicina de Santa Catarina. 2015. (Congresso).
11. V Semana de Iniciação Científica do Curso de Biomedicina. 2015. (Outra).
12. V Simpósio Biomédico e VI Semana de iniciação Científica do Curso de Biomedicina. Avaliação toxicológica in vivo, in vitro e in silico do extrato e compostos isolados das partes aéreas de Rubus rosaefolius. 2015. (Simpósio).
13. V Simpósio Biomédico e VI Semana de iniciação Científica do Curso de Biomedicina. 2015. (Simpósio).
14. XIV Seminário de Iniciação Científica. Avaliação toxicológica in vivo, in vitro e in silico do extrato metanólico e compostos isolados das partes aéreas de Rubus rosaefolius. 2015. (Seminário).
15. III Semana de Iniciação Científica do Curso de Biomedicina. 2014. (Outra).
16. IV Simpósio Biomédico e IV Semana de Iniciação Científica da Biomedicina. 2014. (Simpósio).
17. VIII Fórum Internacional CISDEM: Desafios e Avanços em Tecnologia Farmacêutica. 2014. (Congresso).
18. VIII Fórum Internacional CISDEM: Desafios e Avanços em Tecnologia Farmacêutica. Avaliação Toxicológica do Extrato Obtido das Partes Aéreas de Rubus rosaefolius (Rosaceae). 2014. (Congresso).
19. XIII Seminário de Iniciação Científica. 2014. (Seminário).
20. III Simpósio Biomédico da Univali e II Semana de Iniciação Científica do Curso de Biomedicina. 2013. (Simpósio).
21. III Simpósio Biomédico e II Semana de Iniciação Científica. 2013. (Outra).
22. II Semana Acadêmica e I Semana de Iniciação Científica da Biomedicina. 2013. (Outra).

### Organização de eventos, congressos, exposições e feiras

1. SANTIN, J. R. ; DE FAVERI, R. ; VALADARES, M. C. ; **BROERING, M. F.** . I Workshop ABCF-UNIVALI: Atualização em Toxicologia Clínica e Experimental. 2018. (Outro).

## Educação e Popularização de C & T

---

**Anexo 6. Ficha do aluno****9142 - 11144151 / 1 - Milena Fronza Broering****Email:** milenaibroering@usp.br**Data de Nascimento:** 30/10/1995**Cédula de** RG - 5844437 - SC**Local de** Estado de Santa Catarina**Nacionalidade:** Brasileira**Graduação:** Biomédica - Universidade do Vale do Itajaí - Santa Catarina - Brasil - 2016**Mestrado:** Mestra em Ciências Farmacêuticas (1) - Universidade do Vale do Itajaí - Santa Catarina - Brasil - 2019**Curso:** Doutorado**Programa:** Farmácia (Fisiopatologia e Toxicologia)**Modalidade:** Acadêmica**Área:** Fisiopatologia**Data de Matrícula:** 11/02/2019**Início da Contagem de Prazo:** 11/02/2019**Data Limite para o Depósito:** 06/02/2024**Orientador:** Prof(a). Dr(a). Sandra Helena Poliselli Farsky - 11/02/2019 até o presente Email: sfarsky@usp.br**Proficiência em Línguas:**

Inglês, Aprovado em 11/02/2019

**Data de Aprovação no Exame de Qualificação:** Aprovado em 11/08/2021**Estágio no Exterior:** University of Massachusetts, Estados Unidos da América - Período de 15/11/2022 até 14/11/2023
